ABSTRACT

This dissertation presents an algorithm utilizing four unitarily equivalent representations of the Hankel operator to estimate the Hankel singular values of fractional-order systems based on the Rayleigh-Ritz method. This algorithm is applied to estimate the first ten Hankel singular values for systems of the forms $\frac{a}{s^{\gamma} + a}$ for $a \in \mathbb{R}_+$ and $\frac{1}{s^{\gamma} + 1}$ for $q \in (0, 2)$. Error bounds are generated for each Hankel singular value estimate. The algorithm is also applied to two physical fractional-order systems, the resistor-terminated and inductor-terminated semi-infinite lines, to show how it can be used. Hankel norms are also approximated for conjugate-order systems of the form $\frac{1}{s^{\gamma} + 1} + \frac{1}{s^{\gamma} + 1}$ for a variety of $q \in \mathbb{C}$ to highlight the flexibility of the algorithm in Hankel-norm computation for a wide variety of systems.
ACKNOWLEDGEMENTS

I would like to thank Dr. Tom T. Hartley for his support, example, and enthusiasm. His understanding of fractional-order systems has helped shape my understanding greatly. I would also like to thank Dr. Robert J. Veillette for pushing me toward excellence and for his expertise in $H_\infty$ control. I would like to thank Dr. J. Alexis de Abreu-Garcia for his confidence in me, both in research and teaching. Also, I would also like to thank Dr. D. Dane Quinn and Dr. Gerald W. Young for helping me discover ways to explain things more clearly. I would like to thank Dr. J. Patrick Wilber for his influence in my understanding of functional analysis. The whole faculty in the Department of Electrical and Computer Engineering and in the Department of Theoretical and Applied Mathematics has been very helpful in my time at the University of Akron.

I appreciate the support and encouragement of my family, namely my wife Lynn, my parents Lawrence and Beth Ann Adams, and my wife’s parents, Ren and Cathy Schwartz. I am thankful for friends throughout my schooling and from the Boys J.I.M. Club of America for their continual support.

Finally, I would like to thank my Creator, without whom none of this would be possible.

CHAPTER I
INTRODUCTION

The fractional-order calculus generalizes the order of differentiation and integration from integers to all complex numbers. The subject traditionally has been said to originate from the notation of Leibnitz for the $n^{th}$ derivative, $\frac{d^n f}{dx^n}$. Rather than being limited to $n^{th}$-order iterated derivatives and integrals with $n \in \mathbb{N}$, with the fractional-order calculus it is possible to have half-order, three-quarter-order, $\pi$-order, or $\sqrt{-1}$-order derivatives. As the possible orders are more than just fractions, the fractional-order calculus might more accurately be called the calculus of non-integer order. However, the term fractional-order calculus is an historic one, and will be used throughout the rest of this work.

Systems with fractal physical arrangements or spatially distributed variables, which cannot easily be modeled using the integer-order calculus, may be represented compactly by a fractional-order transfer function. Some of the applications of fractional-order calculus include systems with both energy dissipation and energy storage behavior such as viscoelasticity [12, 27, 37, 79], diffusive transport [57, 25, 42, 55], electrochemical processes and corrosion [62, 63, 64], fluid flow [22, 23, 17], rheology [85, 13, 11, 38, 59], and dynamic processes in porous and self-similar structures [70, 71].
Little attention has been given to Hankel operators for fractional-order systems. The Hankel operator, which maps the past inputs of a given system to its future outputs, is a valuable tool in system analysis, model reduction, and controller synthesis for integer-order systems. For these uses the spectral decomposition of the Hankel operator of the system must be well-understood. In the case of fractional-order systems, this requires a function analytic approach [24] as opposed to the more convenient state-space approach that is available for systems of integer order [86].

The spectral decomposition of fractional-order operators has had very limited study [28]. What study has occurred in this area was done using weighted $L_2$ spaces. It is the aim of this thesis to obtain estimates on the singular values of the Hankel operators for a variety of fractional-order systems in the non-weighted space $L_2(\mathbb{R})$. The largest of these singular values is the Hankel norm, which is the maximum ratio of the energy that can be retrieved from the system in the future to the energy put into the system in the past. The $(k + 1)^{th}$ singular value represents a lower bound on the Hankel-norm error between a system and a $k^{th}$-order approximation to the system [75].

This dissertation presents the background and theory necessary to consider the spectral decomposition of the Hankel operator for fractional-order systems. An algorithm for estimating the Hankel singular values of a fractional-order system using four isomorphic Hilbert spaces is presented. The first ten Hankel singular values for systems of the form $G(s) = \frac{1}{s^{q+1}}$ for $q \in (0, 2)$ are estimated with bounds on the error of the estimation. Also estimated are the Hankel norms for systems of the
form $G(s) = \frac{1}{s^{q+1}} + \frac{1}{s^{q+1}}$ for various $q \in \mathbb{C}$. The estimates are calculated in $\ell_2(\mathbb{N})$.

The bounds on the error of the estimates, which are calculated in $H_2(\mathbb{D})$, are more difficult to compute than the estimates themselves. The estimates and the bounds are calculated for the first ten Hankel singular values of two physical fractional-order systems, the resistor-terminated and inductor-terminated semi-infinite lines. The bounds indicate that the relative errors in the Hankel singular value estimates are each less 17%.

To begin, Chapter 2 presents a review of integer-order systems. Some of the results for differentiation and integration are used later in formulating the definitions of fractional differintegral operators. Also presented are results on bilateral Laplace transforms, differential equations, transfer functions, and convolution operators, which will be used in the analysis of fractional-order systems.

Chapter 3 begins the discussion on fractional-order operators by defining the gamma function and the Mittag-Leffler Function. The Grünwald-Leitnikov, Riemann-Liouville, and Caputo definitions of the non-integer-order differintegral are given. The Laplace transform, fractional-order differential equations, and fractional-order transfer functions are discussed. Fractional-order impulse responses, approximations of fractional-order systems, and initialization of fractional-order systems are highlighted.

Chapter 4 discusses the extension of fractional-order systems to conjugate-order systems. First, pairs of complex-conjugate complex-order differintegrals are considered. It is demonstrated that this differintegral pairing has a real-valued impulse response. The fundamental, linear conjugate-order system $G(s) = \frac{r}{s^{q-\alpha}} + \frac{r}{s^{q-\beta}}$
is considered in detail. The real-valued impulse response for $G(s)$ is developed. Also the pole locations of $G(s)$ are shown. For a given $a$, the set of $q$ for which $G(s)$ corresponds to a stable, causal system are developed, and examples for several $a$ are given. Similarly, for a given $q$, the set of $a$ for which $G(s)$ corresponds to a stable, causal system are developed, and examples for various $q$ are given.

Chapter 5 contains a background on Hilbert-space operators. The most important result is the Spectral Theorem for Compact Hermitian Operators. Chapter 5 also describes linear integral operators on $L_2(\mathbb{R})$, which include the convolution operators. The use of convolution operators in integer-order systems is described. The chapter concludes with a method for estimating the eigenvalues of a compact Hermitian operator on a Hilbert space.

Chapter 6 discusses Hankel operators. Representations as operators on the Hilbert spaces $L_2(\mathbb{R}_+)$, $H_2(\mathbb{C}^+)$, $H_2(\mathbb{D})$, and $\ell_2(\mathbb{N})$ are given. The Nehari problem and its solution are given. The applications of Hankel operators to both the model-reduction problem and to $H_\infty$-control are also discussed. Hankel operators for fractional-order systems are considered, and it is shown that such Hankel operators have infinite rank. The conditions under which the Hankel operator for systems of the form $G(s) = \frac{r}{s^{\alpha}} + \frac{r}{s^{\beta}}$ is compact are also shown.

In Chapter 7 an algorithm to estimate the Hankel singular values for a fractional-order system is presented. The first ten Hankel singular values for the class of systems $\frac{a}{s^{2} - a}$ are determined for several $a$. The first ten Hankel singular values for the class of systems $\frac{1}{s^{q+1}}$ are determined for a variety of $q \in (0, 2)$. 

4
Chapter 8 presents estimates of the Hankel norm for a class of conjugate-order systems. The set of $q$ for which $\frac{1}{s^{q+1}} + \frac{1}{s^{q+1}}$ corresponds to a compact operator is given. Estimates of the Hankel norms for this class of conjugate-order systems are then given.

Chapter 9 considers the conclusions that may be drawn in this dissertation. Also presented is a discussion of future work.
CHAPTER II
A REVIEW OF INTEGER-ORDER SYSTEMS

The background material begins with a review of linear, time-invariant, integer-order systems. We give definitions of iterated derivatives and integrals, which will later be generalized, yielding the definitions of the fractional-order differintegral. The bilateral Laplace transform, as well as ordinary integer-order differential equations and integer-order transfer functions are discussed to provide a familiar context for comparison with ordinary fractional-order differential equations and fractional-order transfer functions. Finally, in this chapter the representation of an integer-order system as a convolution operator is discussed.

2.1 Derivatives and Integrals

The integer-order or ordinary calculus begins with the definition of a derivative. The first derivative is defined by

$$\frac{d}{dt} f(t) = \lim_{\Delta t \to 0} \frac{f(t) - f(t - \Delta t)}{\Delta t}, \quad (2.1)$$
if this limit exists. For any $n \in \mathbb{N}$, this definition may be iterated, yielding

$$\frac{d^n}{dt^n} f(t) = \lim_{\Delta t \to 0} (\Delta t)^{-n} \sum_{k=0}^{n} (-1)^k \left( \frac{n!}{k!(n-k)!} \right) f(t - k\Delta t). \quad (2.2)$$

For convenience, we denote the $n$th-order derivative for a function defined on the interval $[a, b]$ by

$$\frac{d^n}{dt^n} f(t) = a_d^t f(t) \quad (2.3)$$

for all $t \in (a, b]$. This notation is used for fractional-order derivatives, so for consistency it will be retained for integer-order derivatives, even though an integer-order derivative does not require the left-hand endpoint $a$ to be specified. The subscript $t$, for the causal differential operator, denotes the variable with respect to which the differentiation occurs.

The notation used in Equation 2.3 can be extended to apply to iterated integrals as

$$a_d^t f(t) = \int_a^t \int_a^\tau f(\tau) d\tau \, d\xi, \quad (2.4)$$

and so forth.

Without loss of generality, we let the lower limit of the integrals be zero. According to Fubini’s theorem, the order of integration in Equation 2.5 can be reversed,
provided that \( \int_0^\infty |f(t)| \, dt < \infty \). This yields the result
\[
0^d t^{-2} f(t) = \int_0^t \int_0^\xi f(\tau) d\tau d\xi \\
= \int_0^t \int_\tau^t f(\tau) d\xi d\tau \\
= \int_0^t f(\tau) \int_\tau^t d\xi d\tau \\
= \int_0^t f(\tau) (t - \tau) \, d\tau.
\]

The formula can be iterated, resulting in
\[
0^d t^{-n} f(t) = \frac{1}{(n-1)!} \int_0^t (t - \tau)^{n-1} f(\tau) d\tau,
\] (2.6)
which is Cauchy’s formula for iterated integrals. This formula will be generalized in Chapter 3 to include non-integer values of \( n \).

2.2 The Laplace Transform

The bilateral Laplace transform of a function \( f(t) \) denoted by \( F(s) \) is given by
\[
F(s) = \mathcal{L} \{ f(t) \} = \int_{-\infty}^\infty f(t) e^{-st} \, dt,
\] (2.7)
if the integral converges for some values of \( s \) in the complex plane [67]. The set of \( s \) for which the integral converges is called the region of convergence for the Laplace
transform and is denoted by $\mathcal{R}$. The following theorem gives a result concerning the region of convergence.

**Theorem 2.2.1** Let $F(s) = \mathcal{L}\{f(t)\}$ with region of convergence $\mathcal{R}$. Then $F(s)$ is analytic in $\mathcal{R}$.

**Proof** See [61].

The following theorem details some properties of the bilateral Laplace transform. One such property involves the convolution of two functions. Recall the definition of convolution.

**Definition** The convolution of two functions, $f(t)$ and $g(t)$, defined on $\mathbb{R}$ is denoted $(f * g)(t)$ and is defined by

$$(f * g)(t) = \int_{-\infty}^{\infty} f(t - \tau)g(\tau)d\tau.$$  \hfill (2.8)

**Theorem 2.2.2** (Properties of the Bilateral Laplace Transform) Let $F(s) = \mathcal{L}\{f(t)\}$. Then,

1. $\mathcal{L}\{f(t - t_0)\} = e^{-st_0}F(s)$
2. $\mathcal{L}\{f(at)\} = \frac{1}{|a|}F\left(\frac{s}{a}\right)$
3. $\mathcal{L}\{(f_1 * f_2)(t)\} = F_1(s)F_2(s)$
4. $\mathcal{L}\left\{\frac{d}{dt}f(t)\right\} = sF(s)$
5. $\mathcal{L}\left\{\int_{-\infty}^{t} f(\tau)d\tau\right\} = \frac{1}{s}F(s)$

**Proof** See [67].
A useful consequence of Part 4 of Theorem 2.2.2 is that the Laplace transform converts a differential equation into an algebraic equation. An analogous property applying to fractional-order derivatives will be introduced in Chapter 3.

2.3 Differential Equations and Transfer Functions

**Definition** An ordinary integer-order linear constant-coefficient differential equation is an equation of the form

\[
\sum_{k=0}^{n} a_k \frac{d^k}{dt^k} x(t) = \sum_{k=0}^{m} b_k \frac{d^k}{dt^k} f(t), \tag{2.9}
\]

with \(a_n \neq 0\) and \(b_m \neq 0\) where \(f(t)\) is called the forcing function. Assuming \(n \geq m\), \(n\) is the order of the differential equation.

Differential equations of this form are linear and time-invariant; that is, if \(x_1(t)\) and \(x_1(t)\) are the solutions of the differential equation equation with the forcing functions \(f_1(t)\) and \(f_2(t)\), respectively, and \(\alpha_1, \alpha_2 \in \mathbb{C}\), then \(\alpha_1 x_1(t) + \alpha_2 x_2(t)\) is the solution of the differential equation with forcing function \(\alpha_1 f_1(t) + \alpha_2 f_2(t)\) and \(x_1(t + t_0)\) is the solution of the differential equation with forcing function \(f(t + t_0)\) for any \(t_0 \in \mathbb{R}\). Systems that satisfy these two properties are called linear time-invariant systems. Only linear time-invariant systems will be considered in this dissertation.
Using the differentiation property of the Laplace transform, Equation 2.9 can be transformed into the equation,

$$\sum_{k=0}^{n} a_k s^k X(s) = \sum_{k=0}^{m} b_k s^k F(s),$$

where $X(s) = \mathcal{L}\{x(t)\}$ and $F(s) = \mathcal{L}\{f(t)\}$. The transfer function $G(s)$ is defined by

$$G(s) = \frac{X(s)}{F(s)} = \sum_{k=0}^{m} \frac{b_k s^k}{\sum_{k=0}^{n} a_k s^k}.$$

(2.10)

The system impulse response, denoted as $\tilde{g}(t)$, is defined by

$$\tilde{g}(t) = \mathcal{L}^{-1}\{G(s)\}.$$

Let $\mathbb{R}[s]$ denote the set of all polynomials in $s$ with coefficients in $\mathbb{R}$ and let $\mathbb{R}(s)$ denote the set of all ratios of elements in $\mathbb{R}[s]$. Define $A(s) = \sum_{k=0}^{n} a_k s^k$ and $B(s) = \sum_{k=0}^{m} b_k s^k$ with real coefficients. Note that $A(s), B(s) \in \mathbb{R}[s]$ and that $\frac{B(s)}{A(s)} = G(s) \in \mathbb{R}(s)$. By the Fundamental Theorem of Algebra, $A(s)$ has $n$ roots, and $B(s)$ has $m$ roots, and these roots are either real or occur in complex-conjugate pairs.

**Definition** The roots of $A(s)$ are the poles of $G(s)$, and the roots of $B(s)$ are the zeroes of $G(s)$. Denote the poles by $\{p_k\}_{k=1}^{n}$ and the zeroes by $\{z_k\}_{k=1}^{m}$.

Partial-fraction expansion can be used on $G(s)$ to obtain a finite sum of first-order terms in $\mathbb{C}(s)$. Let $p_k$ be the $k^{th}$ pole of $G(s)$, with multiplicity $m_k$. Then a
transfer function for a system can be written as

\[ G(s) = \frac{\sum_{k=0}^{m} b_k s^k}{\sum_{k=0}^{n} a_k s^k} = \sum_{k=1}^{k_n} \sum_{i=1}^{m_k} \frac{r_{ki}}{(s - p_k)^r}. \]  

(2.11)

Note that if a pole or partial-fraction coefficient is complex, its complex conjugate is also a pole or partial-fraction coefficient. Let

\[ \mathcal{U}_s(t) = \begin{cases} 
1, & t \in [0, \infty) \\
0, & t \in (-\infty, 0) 
\end{cases} \]

be the unit step function. Utilizing the Laplace transform pairs,

\[ \mathcal{L}\left\{ \frac{t^{m-1} e^{bt}}{(m-1)!} \mathcal{U}_s(t) \right\} = \frac{1}{(s - b)^m}, \quad \text{Re} (s) > \text{Re} (b) \]

\[ \mathcal{L}\left\{ \frac{t^{m-1} e^{bt}}{(m-1)!} \mathcal{U}_s(-t) \right\} = \frac{1}{(b - s)^m}, \quad \text{Re} (s) < \text{Re} (b) \]

given in [61], then the impulse response \( \tilde{g}(t) \) for the original differential equation is

\[ \tilde{g}(t) = \sum_{k=1}^{k_n} \sum_{i=1}^{m_k} \frac{r_{ki} t^{i-1} e^{p_k t}}{(i-1)!} \mathcal{U}_k(t), \]  

(2.12)

where \( \mathcal{U}_k(t) = \pm \mathcal{U}_s(\pm t) \) depending on the causality and multiplicity of the \( k \text{th} \) mode of response.

We now consider linear, time-invariant, integer-order systems as convolution operators.
2.3.1 Convolution Operators

For a given system, or differential equation, \( G(s) \) is fixed. Let \( \tilde{g}(t) = \mathcal{L}^{-1}\{G(s)\} \), and note that the solution of the differential equation can be written as

\[
x(t) = \mathcal{L}^{-1}\{X(s)\} = \mathcal{L}^{-1}\{G(s)F(s)\} = (\tilde{g} \ast f)(t)
\]  

(2.13)

by the convolution property of Theorem 2.2.2. Hence if \( f(t) \) is the input and \( x(t) \) the output of a system, then the system can be represented by the equation

\[
x(t) = (\tilde{g} \ast f)(t) = \int_{-\infty}^{\infty} \tilde{g}(t-\tau)f(\tau)d\tau = (\mathcal{G}f)(t),
\]

(2.14)

where \( \mathcal{G} \) denotes the convolution operator. \( \mathcal{G} \) is causal if \( \tilde{g}(t) = 0 \) for all \( t < 0 \). \( \mathcal{G} \) is anti-causal if \( \tilde{g}(t) = 0 \) for all \( t > 0 \) [24]. The function \( \tilde{g}(t-\tau) \) is called the kernel of the convolution operator.

The response \( x(t) \) of a system to an input \( f(t) \) is given in the Laplace domain as \( X(s) = G(s)F(s) \). Recall that \( x(t) = (\tilde{g} \ast f)(t) \) or \( x(t) = (\mathcal{G}f)(t) \) as defined by Equation 2.14. For \( t > 0 \), the integral in Equation 2.14 can be broken up as

\[
x(t) = (\mathcal{G}f)(t) = x_{ic}(t) + x_{f}(t)
\]

\[
= \int_{-\infty}^{0} \tilde{g}(t-\tau)f(\tau)d\tau + \int_{0}^{\infty} \tilde{g}(t-\tau)f(\tau)d\tau.
\]

(2.15)
Here, \( x_u(t) = \int_{-\infty}^{0} \hat{g}(t-\tau) f(\tau) d\tau \) is the response of the system to the input applied for \( t < 0 \). This component of the response can be thought of as that which results from initial conditions set up at \( t = 0 \) by the input applied for \( t < 0 \). Thus, we may call it the initial condition response. It is sometimes called the zero-input response.

The other component of the solution \( x_f(t) = \int_{0}^{\infty} \hat{g}(t-\tau) f(\tau) d\tau \) is the forced response, also called the zero-state response. We will return to convolution operators after we have built some general theory about operators.

2.4 Examples

We now consider two examples. The first is an integer-order system, and the second motivates the need for an understanding of fractional-order systems.

2.4.1 A Second-Order System

Consider the differential equation

\[
-\infty d^2_t x(t) + -\infty d_t x(t) + \frac{1}{4} x(t) = -2 -\infty d_t f(t). \tag{2.16}
\]

The transfer function associated with Equation 2.16 is

\[
G(s) = \frac{-2s}{s^2 + s + \frac{1}{4}} = \frac{-2s}{(s + \frac{1}{2})^2} \tag{2.17}
\]
and the impulse response of the system, which is shown in Figure 2.1, is

\[ \tilde{g}(t) = \mathcal{L}^{-1} \{ G(s) \} = e^{-\frac{t}{2}} (t - 2) \mathcal{U}_s(t). \]  

(2.18)

The convolution operator for this system is

\[ (\mathcal{G}f)(t) = \int_{-\infty}^{\infty} e^{-\frac{t-\tau}{2}} (t - \tau - 2) \mathcal{U}_s(t - \tau) f(\tau) d\tau. \]  

(2.19)
For \( t \geq 0 \), the initial condition response is

\[
x_{ic}(t) = \int_{-\infty}^{0} e^{-\frac{t+\tau}{\tau}} (t - \tau - 2) f(\tau) d\tau,
\]

and the forced response is

\[
x_f(t) = \int_{0}^{t} e^{-\frac{t+\tau}{\tau}} (t - \tau - 2) f(\tau) d\tau.
\]

This system has been represented as a differential equation, a transfer function, and a convolution operator. The initial-condition and forced responses have been shown for this system. We will consider this system as an operator on a Hilbert space in Chapter 5.

2.4.2 A Motivating Example

This development follows that of [30]. Suppose that we have a semi-infinite line with resistance per unit length \( R \) and capacitance per unit length \( C \). Define \( \alpha = \frac{1}{RC} \). Then the voltage on the line is given by the integer-order partial differential equation,

\[
\frac{\partial}{\partial t} v(x, t) = \alpha \frac{\partial^2}{\partial x^2} v(x, t),
\]

with \( v(0, t) = v_{in}(t) \) given and \( \lim_{x\to\infty} v(x, t) = 0 \). We will utilize the bilateral Laplace transform denoted \( \mathcal{L} \) to take a function in \( t \) to a function in \( s \) and the unilateral Laplace transform denoted \( \mathcal{L}_+ \) to take a function in \( x \) to a function in \( p \).
The current in the line at \( x \) is given by

\[
i(x, t) = -\frac{1}{R} \frac{\partial}{\partial x} v(x, t).
\] (2.23)

Taking the bilateral Laplace transform in \( t \) of Equation 2.22 gives

\[
sV(x, s) = \alpha \frac{\partial^2}{\partial x^2} V(x, s),
\] (2.24)

with \( V(0, s) = V_{in}(s) = \mathcal{L} \{ v_{in}(t) \} \) and \( \lim_{x \to \infty} V(x, s) = 0 \). We will denote \( V^*(x, s) = \frac{\partial}{\partial x} V(x, s) \) and take the unilateral Laplace transform in \( x \) of Equation 2.24, resulting in

\[
\frac{s}{\alpha} \tilde{V}(p, s) = p^2 \tilde{V}(p, s) - pV(0, s) - V^*(0, s),
\] (2.25)

where \( \tilde{V}(p, \cdot) = \mathcal{L}_+ V(x, \cdot) \). Rearranging and solving for \( \tilde{V}(p, s) \) gives

\[
\tilde{V}(p, s) = \frac{p}{p^2 - \frac{2}{\alpha}} V(0, s) + \frac{1}{p^2 - \frac{2}{\alpha}} V^*(0, s).
\] (2.26)
The unilateral Laplace transform pairs given by 
\[
\frac{p}{p^2 - a^2} = \mathcal{L}_+ \{\cosh (ax)\} \quad \text{and} \quad \frac{a}{p^2 - a^2} = \mathcal{L}_+ \{\sinh (ax)\}
\]
are used to obtain
\[
V(x, s) = \cosh \left( \sqrt{\frac{s}{\alpha}} x \right) V(0, s) + \sqrt{\frac{\alpha}{s}} \sinh \left( \sqrt{\frac{\alpha}{s}} x \right) V^*(0, s)
\]
\[
= \frac{1}{2} \left( e^{\sqrt{\frac{s}{\alpha}} x} + e^{-\sqrt{\frac{s}{\alpha}} x} \right) V(0, s) + \frac{1}{2} \left( e^{\sqrt{\frac{s}{\alpha}} x} - e^{-\sqrt{\frac{s}{\alpha}} x} \right) \left( \sqrt{\frac{s}{\alpha}} \right) V^*(0, s)
\]
\[
= \frac{1}{2} e^{\sqrt{\frac{s}{\alpha}} x} \left( V(0, s) + \sqrt{\frac{\alpha}{s}} V^*(0, s) \right) + \frac{1}{2} e^{-\sqrt{\frac{s}{\alpha}} x} \left( V(0, s) - \sqrt{\frac{\alpha}{s}} V^*(0, s) \right)
\]
(2.27)

Note that \( \sqrt{s} \) is not analytic on the negative real axis \( \mathbb{R}_- \). Since \( \alpha \) is a non-negative real number, \( \sqrt{\frac{s}{\alpha}} \) is not analytic on \( \mathbb{R}_- \). Subsequently, \( V(x, s) \) is not analytic with respect to \( s \) for \( s \in \mathbb{R}_- \). Therefore by Theorem 2.2.1, \( \mathbb{R}_- \not\subset \mathcal{R} \). For \( s \in \mathcal{R} \), \( |\arg(s)| < \frac{\pi}{2} \). It follows that for \( s \in \mathcal{R} \), \( |\arg \left( \sqrt{\frac{s}{\alpha}} \right) | < \frac{\pi}{2} \). Subsequently, for \( s \in \mathcal{R} \), \( \Re \left( \sqrt{\frac{s}{\alpha}} \right) > 0 \).

Since \( \lim_{x \to \infty} V(x, s) = 0 \), the first term in Equation 2.27 must be zero. Hence,
\[
V(0, s) + \sqrt{\frac{\alpha}{s}} V^*(0, s) = 0. \quad (2.28)
\]

Taking the bilateral Laplace transform of Equation 2.23 gives
\[
I(x, s) = -\frac{1}{R} \frac{\partial}{\partial x} V(x, s) = -\frac{1}{R} V^*(x, s).
\]
Hence, Equation 2.28 can be written as

\[ V(0, s) = R\sqrt{\alpha}\frac{1}{\sqrt{s}} I(0, s). \]

We can therefore write the impedance of the lossy semi-infinite line at \( x = 0 \) as

\[ Z(0, s) = \frac{V(0, s)}{I(0, s)} = R\sqrt{\alpha}\frac{1}{\sqrt{s}} = \sqrt{\frac{R}{C}} \frac{1}{\sqrt{s}}. \]

(2.29)

We define the constant

\[ A = \sqrt{\frac{R}{C}}, \]

and Equation 2.29 can be written as

\[ Z(0, s) = \frac{V(0, s)}{I(0, s)} = \frac{A}{\sqrt{s}}. \]

(2.30)

The circuit symbol for the lossy semi-infinite line is shown in Figure 2.2.
We will see in Chapter 3, that the differential equation associated with Equation 2.30 is

\[ i(0,t) = \frac{1}{A} \int_{-\infty}^{t} d_{\alpha}^{4} v(0,t). \]

This is an extension of the order of a derivative from integer orders to non-integer orders.

2.5 Conclusions

In this chapter we have reviewed integer-order systems. These systems have been represented as differential equations, transfer functions, and convolution operators. An example has been presented that demonstrates these concepts. A motivating example has been given that illustrates the need for an understanding of fractional-order systems. We now introduce differentiation and integration of non-integer order.
CHAPTER III
FRACTIONAL-ORDER CALCULUS

The fractional calculus is the generalization of the integer-order, or ordinary, calculus to differentiation and integration of non-integer order. Several fairly comprehensive works have been written in recent years on the subject [66, 58, 83, 77, 43].

Two special functions that are often used in discussions of fractional-order systems are presented. Next, three common definitions of the fractional-order differential and the conditions under which the definitions are equivalent are discussed. The impulse response for a fractional-order system, which is essential to the associated convolution and Hankel operators is derived. We present original material pertaining to the consideration of fractional-order systems of complex order in both the time and frequency domains. A finite-dimensional approximation technique for fractional-order systems is presented. Finally, the problem of proper initialization of fractional-order systems, which is directly related to the Hankel operator, is discussed.

3.1 Special Functions

We begin by defining two special functions, the gamma function and the Mittag-Leffler function, which are heavily used in the fractional-order calculus.
3.1.1 The Gamma Function

The gamma function is defined for positive \( q \) by [65] as

\[
\Gamma(q) = \int_0^\infty t^{q-1}e^{-t}dt. \tag{3.1}
\]

Note that for \( q \in \mathbb{N} \), \( \Gamma(q + 1) = q! \). A more comprehensive definition is given by

\[
\Gamma(q) = \lim_{n \to \infty} \left( \frac{(n + 1)^q}{q \left(1 + \frac{q}{1}\right) \left(1 + \frac{q}{2}\right) \cdots \left(1 + \frac{q}{n-1}\right) \left(1 + \frac{q}{n}\right)} \right). \tag{3.2}
\]

Either definition can apply for \( q \in \mathbb{C} \). The gamma function is the only analytic continuation of the factorial function to the complex plane [19].

Based on the definition of the gamma function given in Equation 3.1, the lower and upper incomplete gamma functions, \( \gamma(q, x) \) and \( \Gamma(q, x) \), respectively, can be defined by

\[
\gamma(q, x) = \int_0^x t^{q-1}e^{-t}dt \tag{3.3}
\]

and

\[
\Gamma(q, x) = \int_x^\infty t^{q-1}e^{-t}dt. \tag{3.4}
\]

The complete gamma function plays a key role in the definitions of fractional-order differintegral operators. The lower incomplete gamma function appears in the impulse response of systems of the form \( G(s) = \frac{1}{s^{\frac{1}{n}} - a} \).
3.1.2 The Mittag-Leffler Function

The Mittag-Leffler function is the entire function defined \[72\] by the series

\[
\mathcal{E}_\alpha(z) = \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(\alpha k + 1)}.
\]  

(3.5)

If \( \alpha = 1 \), then

\[
\mathcal{E}_1(z) = \sum_{k=0}^{\infty} \frac{z^k}{k!} = e^z.
\]

A more generalized Mittag-Leffler function can be defined by

\[
\mathcal{E}_{\alpha,\beta}(z) = \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(\alpha k + \beta)}.
\]  

(3.6)

The Laplace transform of a specially time-weighted Mittag-Leffler function is given by

\[
\mathcal{L} \{t^{\beta-1} \mathcal{E}_{\alpha,\beta}(at^\alpha)\} = \frac{1}{s^\beta (1 - as^{-\alpha})}.
\]  

(3.7)

This Laplace transform pair will be used in one formulation of the impulse response of a simple fractional-order system.

3.2 Definitions

The definitions of the fractional-order calculus typically involve taking a definition in the ordinary calculus and generalizing it to non-integer order.
3.2.1 The Grünwald-Leitnikov Definition

The Grünwald-Leitnikov definition generalizes the iterated derivative given in Equation 2.2 by replacing $n$ with any $q \in \mathbb{C}$ and $n!$ by $\Gamma(q + 1)$, giving

$$a_d^q f(t) = \lim_{\Delta t \to 0} (\Delta t)^{-1} \sum_{k=0}^{\infty} (-1)^k \frac{\Gamma(q + 1)}{\Gamma(k + 1)\Gamma(q - k + 1)} f(t - k\Delta t).$$

(3.8)

Note that $a$ is not yet needed. An equivalent definition [66] is

$$a_d^q f(t) = \lim_{N \to \infty} \sum_{k=1}^{N} \frac{\Gamma(k - q)}{\Gamma(k + 1)} f \left( t - k \left( \frac{t - a}{N} \right) \right).$$

(3.9)

Note that this definition uses $a$. The Grünwald-Leitnikov definition is best suited for discrete-time simulation of fractional-order systems and implementation of fractional-order system using digital signal processors and field programmable gate arrays [18], [41], [40].

3.2.2 The Riemann-Liouville Definition

The Riemann definition arises from generalizing Cauchy’s formula for iterated integrals, Equation 2.6. The result is, for $q < 0$

$$a_d^q f(t) = \frac{1}{\Gamma(-q)} \int_a^t (t - \tau)^{-q-1} f(\tau) d\tau.$$  

(3.10)

The same expression holds for $q \in \mathbb{C}^-$. The integral does not converge if Re $(q) \geq 0$. The first extension to Re $(q) \geq 0$ is the Riemann-Liouville definition of the fractional
differintegral. Choose \( r < 0 \) and \( n \in \mathbb{N} \) such that \( q = r + n \). Then, due to composition of differintegrals,

\[
\frac{a}{d_t^n} f(t) = \frac{a}{d_t^{r+n}} f(t) = \frac{a}{d_t^n} \frac{a}{d_t^r} f(t)
\]

\[
= \frac{d^n}{dt^n} \frac{1}{\Gamma(-r)} \int_a^t (t - \tau)^{-r-1} f(\tau) d\tau.
\]  

(3.11)

This is the same as taking the \( n^{th} \) derivative of the \((q - n)^{th}\) fractional integral of a function.

3.2.3 The Caputo Derivative

The Caputo derivative is a generalization of Equation 3.10 defined by

\[
\frac{\partial^n}{\partial t^n} \frac{1}{\Gamma(-r)} \int_a^t (t - \tau)^{-r-1} \frac{d^n}{d\tau^n}f(\tau) d\tau.
\]  

(3.12)

This is equivalent to taking the \((q - n)^{th}\) fractional integral of the \( n^{th} \) derivative of a function. This is not the same as the Riemann-Liouville definition given in Equation 3.11. Consider, for example, the semiderivative of the unit step function, \( \mathcal{U}_a(t) \) for \( a > 0 \). In this case \( \frac{\partial}{\partial t} \mathcal{U}_a(t) = 0 \neq \frac{t^{q-1}}{1(q)} = \frac{a}{d_t^q} \mathcal{U}_a(t) \).

3.2.4 Comparison of the Definitions

With some restrictions of functions, the Riemann-Liouville and Grünwald-Leitnikov derivatives are equivalent [77]. Let \( f(t) \) be \((n - 1)\)-times continuously differentiable in the interval \([a, T]\) with \( f^{(n)}(t) \) integrable over \([a, T]\). Then for every \( p \) such that
0 < p < n, the Riemann-Liouville derivative exists and coincides with the Grünwald-Leitnikov derivative.

Similarly, if the lower limit of the interval on which the derivatives are acting is \(-\infty\), and \(f(t)\) and its derivatives behave reasonably as \(t \to -\infty\), then the Riemann-Liouville and Caputo derivatives are equivalent [77].

3.3 The Laplace Transform of Fractional-Order Differintegrals

Since the Laplace transform is utilized heavily in system analysis and control, the Laplace transform of the \(q\)th-order differintegral is required. Since \(\mathcal{L}\{ -\infty d_t^p f(t) \} = s^n \mathcal{L}\{ f(t) \}\) for \(n \in \mathbb{Z}\), it would be convenient if \(\mathcal{L}\{ -\infty d_t^q f(t) \} = s^q \mathcal{L}\{ f(t) \}\) for \(q \in \mathbb{C}\).

Fortunately, this is the case.

**Theorem 3.3.1** Let \(f(s) = \mathcal{L}\{ f(t) \}\), then the Laplace transform of a \(q\)th-order derivative is given by

\[
\mathcal{L}\{ -\infty d_t^q f(t) \} = s^q F(s). 
\] (3.13)

**Proof** See [77].

3.4 Fractional-Order Systems

We now consider differential equations, transfer functions, and convolution operators for fractional-order systems.
3.4.1 Fractional-Order Differential Equations

**Definition** A fractional-order differential equation is a relation,

\[
\sum_{k=1}^{n} a_k -\infty d_t^{\nu_k} x(t) = \sum_{k=1}^{m} b_k -\infty d_t^{\mu_k} u(t),
\]

where \(\{q_n\}_{n=1}^N \subset \mathbb{C}\) and \(\{r_n\}_{n=1}^M \subset \mathbb{C}\). If there exist \(\{\xi_n\}_{n=1}^N \subset \mathbb{N}\) and \(\{\rho_n\}_{n=1}^M \subset \mathbb{N}\) and \(\nu \in \mathbb{C}\) such that \(q_n = \xi_n \nu\) for all \(1 \leq n \leq N\) and \(r_n = \rho_n \nu\) for all \(1 \leq n \leq M\), then the differential equation is said to be of commensurate order.

Note that any differential equation with \((\{q_n\}_{n=1}^N \cup \{r_n\}_{n=1}^M) \subset \mathbb{Q}\) is commensurate-order.

**Definition** The fundamental fractional-order differential equation is the differential equation given by

\[
-\infty d_t^n x(t) - ax(t) = u(t).
\]

3.4.2 Fractional-Order Transfer Functions

As with integer-order differential equations, a fractional-order differential equation may be represented as a transfer function. A system whose differential equation is given by Equation 3.14 can be expressed by the transfer function

\[
G(s) = \frac{\sum_{k=1}^{m} b_k s^{\nu_k}}{\sum_{k=1}^{n} a_k s^{\xi_k}}.
\]
If the differential equation for a system is commensurate-order, then the transfer function is said to be of commensurate order. A commensurate-order transfer function has a partial-fraction-like expansion [9].

We note that, in general, fractional-order transfer functions are multi-valued functions. Although the value of $s$ is periodic in $\arg(s)$ with period $2\pi$, the value of $G(s)$ is either periodic in $\arg(s)$ with period greater than $2\pi$ or aperiodic in $\arg(s)$. As an example consider $G(s) = \frac{1}{\sqrt{s^2 + 2}}$. $1 = e^{i0} = e^{i2\pi}$, but

$$G(e^{i0}) = \frac{1}{\sqrt{e^{i0} + 2}} = \frac{1}{1 + 2} = \frac{1}{3} \neq \frac{1}{1} = \frac{1}{-1 + 2} = \frac{1}{\sqrt{e^{i2\pi} + 2}} = G(e^{i2\pi}) .$$

Note that $G(s)$ has a pole at $s = 4e^{i2\pi}$, but that $G(s)$ is analytic at $s = 4e^{i0}$. For this reason, we make the following definitions.

**Definition** A *Riemann sheet* is the set given by

$$\{ s \in \mathbb{C} : (2n - 1)\pi < \arg s < (2n + 1)\pi \text{ for some } n \in \mathbb{Z} \}.$$  

The set

$$\{ s \in \mathbb{C} : -\pi < \arg s < \pi \}$$

is called the *primary Riemann sheet*.

Note that any mapping of the form $s \mapsto \frac{a}{s^2 - a}$ is single-valued on any Riemann sheet. A fractional-order system is stable and causal if and only if its transfer function is analytic in the right-half plane of the primary Riemann sheet [56]. We will use this fact in our analysis of complex-order systems.

Again, as with integer-order systems, the output of a system may be written as $X(s) = G(s)U(s)$ for a transfer function $G(s)$ and an input $U(s)$. Hence, the operator representing the system, $x(t) = (Gu)(t)$, is the convolution operator given
by

\[ x(t) = (G u) (t) = \int_{-\infty}^{\infty} \tilde{g}(t - \tau) u(\tau) d\tau, \quad (3.17) \]

where \( \tilde{g}(t) \) is the impulse response of the system. Thus we need the impulse response of fractional-order operators.

### 3.4.3 Fractional-Order Impulse Responses

We now discuss three definitions of the fractional-order impulse response that are based on different functions.

#### The \( R \)- and \( F \)-Function Representations

Let \( q \in \mathbb{C} \). The \( F \)-function is defined as the impulse response for the fundamental fractional-order differential equation given in Equation 3.15 [31]. It is obtained by performing long-division on the transfer function of the fundamental fractional-order system. Assuming \(|a| < 1\), we can write

\[
\frac{1}{s^q - a} = \frac{1}{s^q} + \frac{a}{s^{2q}} + \frac{a^2}{s^{3q}} + \frac{a^3}{s^{4q}} + \cdots = \sum_{k=0}^{\infty} \frac{a^k}{s^{(k+1)q}},
\]

\[
(3.18)
\]

Using the Laplace transform pair from [61] given by

\[
\mathcal{L} \left\{ \frac{t^q}{\Gamma (q + 1)} \right\} = \frac{1}{s^{q+1}},
\]

\[
(3.19)
\]
the inverse Laplace transform of the series is taken term by term to give

\[
\mathcal{L}^{-1}\left\{\frac{1}{s^q-a}\right\} = F_q(a, t) = \sum_{k=0}^{\infty} a^{k+1} q^{-1} \frac{a^{k+1} q^{-1}}{\Gamma ((k+1) q)}.
\]  

(3.20)

Similarly, for \( \nu \in \mathbb{C} \), the \( R \)-Function is defined as the impulse response for the differential equation

\[
-\infty d_t^\nu x(t) - ax(t) = -\infty d_t^\nu u(t).
\]

Again, using long division, and assuming \( \left| \frac{\nu}{\pi} \right| < 1, \)

\[
\frac{s^\nu}{s^q-a} = \frac{1}{s^{q-\nu}} + \frac{a}{s^{2q-\nu}} + \frac{a^2}{s^{3q-\nu}} + \frac{a^3}{s^{4q-\nu}} + \cdots \\
= \sum_{k=0}^{\infty} \frac{a^k}{s^{k+1} q^{\nu-1}}.
\]

(3.21)

Using the Laplace transform pair given by Equation 3.19, the inverse Laplace transform of the series is taken term by term to give

\[
R_{q,\nu}(a, t) = \sum_{k=0}^{\infty} a^{k+1} q^{-1-\nu} \frac{a^{k+1} q^{-1-\nu}}{\Gamma ((k+1) q - \nu)}.
\]

(3.22)

Hence the kernels of the convolution operator representations for the systems whose transfer functions are \( \frac{1}{s^q-a} \) and \( \frac{s^\nu}{s^q-a} \) are

\[
\tilde{g}(t - \tau) = F_q(a, t - \tau)
\]

(3.23)
\[ \tilde{g}(t - \tau) = R_{q,\nu}(a, t - \tau), \quad (3.24) \]

respectively.

The Mittag-Leffler Function Representation

Recall that the generalized Mittag-Leffler function, \( \mathcal{E}_{\alpha,\beta} (t) \) is involved in the Laplace-transform pair,

\[ \mathcal{L} \left\{ t^{\beta-1} \mathcal{E}_{\alpha,\beta} (at^\alpha) \right\} = \frac{1}{s^\beta (1 - as^{-\alpha})} \]

as given in 3.7. Then the Laplace transform for the function, \( t^{q-1} \mathcal{E}_{q,q} (at^q) \) is given by

\[ \mathcal{L} \left\{ t^{q-1} \mathcal{E}_{q,q} (at^q) \right\} = \frac{1}{s^q (1 - as^{-q})} = \frac{1}{s^q - a}, \quad (3.25) \]

which indicates that this function using the Mittag-Leffler function is the impulse response for the fundamental fractional-order differential equation. Although in the literature this function is called a Mittag-Leffler differential function, it must be noted that a factor of \( t^{q-1} \) is included, so the impulse response is actually a time-weighted Mittag-Leffler function.

Thus, the kernel of the integral operator representation for the system whose transfer function is \( \frac{1}{s^q - a} \) is

\[ \tilde{g}(t - \tau) = (t - \tau)^{q-1} \mathcal{E}_{q,q} (a(t - \tau)^q). \quad (3.26) \]
When more than one fractional-order derivative is present in the system, the impulse response is more complicated. [77] gives impulse responses for fractional-order differential equations with one, two, three, and four fractional-order differintegrals. The Representation of Miller and Ross

Miller and Ross [58] first define a function, $E_t(q, a)$ by

$$E_t(q, a) = \frac{e^{at}}{a^q \Gamma(q)} \gamma(q, at).$$

This function can be rewritten as

$$E_t(q, a) = \frac{e^{at}}{a^q \Gamma(q)} \int_0^{at} \xi^{q-1} e^{-\xi} d\xi$$

$$= \frac{1}{a^q} \int_0^{at} \frac{\xi^{q-1}}{\Gamma(q)} e^{at-\xi} d\xi$$

$$= \int_0^t e^{a(t-\tau)} \tau^{q-1} \frac{d\tau}{\Gamma(q)}$$

$$= e^{at} \frac{t^{q-1}}{\Gamma(q)}.$$

Hence, it can be seen that

$$\mathcal{L} \{E_t(q, a)\} = \mathcal{L} \{e^{at}\} \mathcal{L} \left\{ \frac{t^{q-1}}{\Gamma(q)} \right\} = \frac{s^{-q}}{s - a}. \quad (3.27)$$
For $n \in \mathbb{N}$, it is an algebra fact that

$$x^n - a^n = (x - a) \left( \sum_{k=1}^{n} a^{k-1} x^{n-k} \right).$$

Subsequently, for $n \in \mathbb{N}$ with $x = \frac{1}{s^{\frac{1}{n}}}$,

$$s - a^n = \left( \frac{1}{s^{\frac{1}{n}}} - a \right) \left( \sum_{k=1}^{n} a^{k-1} s^{1 - \frac{k}{n}} \right),$$

or

$$\frac{1}{s^{\frac{1}{n}} - a} = \frac{\sum_{k=1}^{n} a^{k-1} s^{1 - \frac{k}{n}}}{s - a^n} = \sum_{k=1}^{n} a^{k-1} \frac{s^{1 - \frac{k}{n}}}{s - a^n}.$$  

The inverse Laplace transform of $\frac{1}{s^{\frac{1}{n}} - a}$ is thus,

$$\mathcal{L}^{-1} \left\{ \frac{1}{s^{\frac{1}{n}} - a} \right\} = \mathcal{L}^{-1} \left\{ \sum_{k=1}^{n} a^{k-1} \frac{s^{1 - \frac{k}{n}}}{s - a^n} \right\} = \sum_{k=1}^{n} a^{k-1} \mathcal{L}^{-1} \left\{ \frac{s^{1 - \frac{k}{n}}}{s - a^n} \right\} = \sum_{k=1}^{n} a^{k-1} E_{1} \left( \frac{k}{n} - 1, a^n \right). \quad (3.28)$$

Hence, the kernel of the integral operator for the system whose transfer function is $\frac{1}{s^{\frac{1}{n}} - a}$ is

$$\tilde{g}(t - \tau) = \sum_{k=1}^{n} a^{k-1} E_{1} \left( \frac{k}{n} - 1, a^n \right) \quad (3.29)$$

This representation is advantageous because it involves a finite sum rather than an infinite sum. Thus, the sum and integral sign of the integral operator are inter-
changeable, without having to resort to convergence theorems for integrals. This representation has a disadvantage in that only rational-order systems can be studied.

Equivalence of Convolution Kernels

The three convolution kernels presented above are formed using differently defined functions. We now show, via direct comparison in the time-domain, that the functions are the same for $q = \frac{1}{n}$ for $n \in \mathbb{N}$.

**Theorem 3.4.1** Let $q \in \mathbb{C}$. Then $F_q(a, t) = t^{q-1} \mathcal{E}_{q,q}(at^q)$.

**Proof** Note that using the definition of the generalized Mittag-Leffler function, in Equation 3.6,

$$
t^{q-1} \mathcal{E}_{q,q}(at^q) = t^{q-1} \sum_{k=0}^{\infty} \frac{(at^q)^k}{\Gamma(qk + q)}
= \sum_{k=0}^{\infty} a^k t^{(k+1)q-1} \frac{1}{\Gamma((k+1)q)}
= F_q(a, t),
$$

by the definition of the $F$-function in Equation 3.20. Thus, the convolution kernels are equal. □

**Theorem 3.4.2** Let $n \in \mathbb{N}$ and let $q = \frac{1}{n}$. Then the equality,

$$
F_q(a, t) = t^{q-1} \mathcal{E}_{q,q}(at^q) = \sum_{k=1}^{n} a^{k-1} E_{\frac{k}{n}-1} \left( \frac{k}{n} - 1, a^n \right) \quad (3.30)
$$

holds.
Proof Because the previous theorem establishes the equality of the left and middle terms in Equation 3.30, all that remains is to demonstrate that the middle term is equal to the right term. Consider

\[
\sum_{k=1}^{n} a^{k-1} E_t \left( \frac{k}{n} n - 1, a^n \right) = \sum_{j=1}^{n} a^{j-1} t_n^j - 1 \sum_{k=0}^{\infty} \frac{(a^n t)^k}{\Gamma \left( \frac{\ell n}{n} - 1 + k + 1 \right)}
\]

\[
= \sum_{j=1}^{n} \sum_{k=0}^{\infty} a^{nk+j-1} t_n^{\frac{1}{n} + k - 1} \Gamma \left( \frac{\ell n}{n} + k \right)
\]

\[
= \sum_{k=0}^{\infty} \sum_{j=1}^{n} a^{nk+j-1} \frac{t_n^{\frac{1}{n} + 1} - 1}{\Gamma \left( \frac{nk+j}{n} \right)}
\]

\[
= \sum_{\ell=0}^{\infty} \frac{t_n^{\frac{\ell+1}{n} - 1}}{\Gamma \left( \frac{\ell+1}{n} \right)} \Gamma \left( \frac{\ell+1}{n} \right) \left( a t_n^{\frac{\ell}{n}} \right).
\]

Hence, the equality holds, and the three functions are the same for \( q = \frac{1}{n} \).

These impulse responses will be used to consider the Hankel operator of a fractional-order system in Chapter 7.

3.5 Approximation of Fractional-Order Operators

One method for approximating fractional-order operators is accomplished in the frequency domain. This method was developed by Oustaloup [71] and Chareff et al. [16]. Rational approximations are made for operators of the type \( s^{-q} \) that are within a certain error bound of the operator’s Bode magnitude plot over a defined frequency range. Note that the Bode magnitude plot for \( s^{-q} \) is a line with a slope of \( -20q \frac{\text{dB}}{\text{dec}} \) that is 0dB at 1rad. This approximation method may be accomplished as follows.
First a frequency range, $\omega_a \leq \omega \leq \omega_b$, and error bound, $M_e$, are selected. The pole-to-zero ratio, $a$, and the zero-to-pole ratio, $b$, are defined by

$$a = 10^{\frac{M_e}{\log 10}},$$

and

$$b = 10^{\frac{M_e}{\log 10}},$$

respectively. The number of poles required for the approximation is determined by

$$N - 1 < \frac{\log \left( \frac{\omega_b}{\omega_a} \right)}{\log (ab)} \leq N.$$

The first pole, $p_0$, is placed at $p_0 = \omega_a \cdot 10^{\frac{M_e}{\log 10}}$. Starting at $k = 0$, poles are placed at

$$p_k = (ab)^k \omega_a$$

and, starting at $k = 0$, zeroes are placed at

$$z_k = a^{k+1}b^k \omega_a.$$

Although the slope of the magnitude response is correct, the gain of the approximation is not, so a gain applied to the approximation to match that of the integrator is applied to the system. Table 3.1 gives approximations with 2.5dB-error over $\omega \in [0.01, 100]$
Table 3.1: 2.5dB-Approximations for $s^{-\frac{k}{10}}$ over $\omega \in [0.01, 100]$ for $1 \leq k \leq 9$.

</table>

for $s^{-\frac{k}{10}}$ for $1 \leq k \leq 9$. Hartley and Lorenzo give a similar table for approximations with 2dB-error in [34].

Once the Hankel singular values for a fractional-order system are determined, it will be possible to evaluate how close to the optimal $n$-dimensional approximation an approximation made using the technique of Oustaloup and Charef et al. is. Although it is beyond the scope of this dissertation, if the Schmidt pairs could be determined, then it would be possible to construct the optimal $n$-dimensional approximation to a fractional-order system.

3.6 Initialization of Fractional-Order Systems

Often in real applications, the analysis of a system starts at some initial time $t_0$ with knowledge of the initial state. The initial state contains all of the effect of the past
history of the system. For a \( k \)-th-order system an initial state that is \( k \)-dimensional is required to properly account for the effect of the past.

Because fractional-order systems are infinite-dimensional, they require initializations more complicated than those for integer-order systems. Although it is commonly held that the Caputo derivative properly accounts for initial conditions using a finite number of initial conditions [15], it has been shown that in general, the Caputo initialization cannot account for all types of initialization [2, 3]. The Caputo derivative properly accounts for initial conditions if the system has been held at that initial condition for all time [49, 50, 52]. As such, to account for an arbitrary initialization, an infinite amount of information is necessary [46, 47, 48, 32, 33, 68].

Using the Riemann-Liouville definition, Lorenzo and Hartley derive an initialization function \( \Psi (f, q, -\infty, 0, t) \) as follows.

Without a loss of generality, it can be assumed that the initialization period is \( t \in \mathbb{R}_- \), and that the present problem occurs for \( t \in \mathbb{R}_+ \). Define the initialization function \( \Psi (f, q, -\infty, 0, t) \) by

\[
\Psi (f, q, -\infty, 0, t) = \frac{d^n}{dt^n} \frac{1}{\Gamma(-(q-n))} \int_{-\infty}^{0} (t - \tau)^{-(q-n)-1} f(\tau) d\tau. \tag{3.31}
\]

Recall the definition of the Riemann-Liouville definition of the differintegral

\[
\int_{-\infty}^{t} f(t) d\tau = \frac{d^n}{dt^n} \frac{1}{\Gamma(-r)} \int_{-\infty}^{t} (t - \tau)^{-r-1} f(\tau) d\tau,
\]
where \( n \in \mathbb{N}, r < 0, \) and \( q = r + n. \) Then, for \( t \in \mathbb{R}_+, \)

\[
-\infty d_t^q f(t) = \frac{d^n}{dt^n} \frac{1}{\Gamma(-r)} \int_{-\infty}^{0} (t-\tau)^{-r-1} f(\tau) d\tau + \frac{d^n}{dt^n} \frac{1}{\Gamma(-r)} \int_{0}^{t} (t-\tau)^{-r-1} f(\tau) d\tau
\]

\[
= \frac{d^n}{dt^n} \frac{1}{\Gamma(-r)} \int_{-\infty}^{0} (t-\tau)^{-r-1} f(\tau) d\tau + d_t^q f(t)
\]

\[
= \Psi (f, q, -\infty, 0, t) + d_t^q f(t)
\]

\[
= d_t^q f(t) + \Psi (f, q, -\infty, 0, t).
\]

\( \Psi (f, q, -\infty, 0, t) \) is called the initialization- or psi-function and properly takes into account the initialization of a single differintegral [47].

In general, \( \Psi (f, q, -\infty, 0, t) \) is difficult to use [52, 51, 53]. As an example, consider the system whose differential equation is

\[
-\infty d_t^q x(t) + \alpha x(t) = \beta u(t) \tag{3.32}
\]

with an initial time of \( t = 0. \) That is, we wish to analyze the system whose differential equation is

\[
0 d_t^q x(t) + \alpha x(t) = \beta u(t). \tag{3.33}
\]

However, there is a loss of information changing the differential equation from Equation 3.32 to Equation 3.33. We must modify Equation 3.33 to become

\[
0 d_t^q x(t) + \Psi (x, q, -\infty, 0, t) + \alpha x(t) = \beta u(t). \tag{3.34}
\]
We will make the substitution

\[ \xi(t) = x(t) + _0^a d_{t}^{-q} \Psi (x, q, -\infty, 0, t). \]  

Equation 3.34 becomes

\[ _0^d_t \xi(t) + \alpha \xi(t) = \beta u(t) + \alpha _0^d_t d_{t}^{-q} \Psi (x, q, -\infty, 0, t), \]  

which we can write as the convolution operator

\[ \xi(t) = \int_0^t F_q (\alpha, t - \tau) \left( \beta u(\tau) + \alpha _0^d_t d_{\tau}^{-q} \Psi (x, q, -\infty, 0, \tau) \right) d\tau \]  

Thus, the solution to Equation 3.33 properly accounting for initialization is

\[ x(t) = \int_0^t F_q (\alpha, t - \tau) \left( \beta u(\tau) + \alpha _0^d_t d_{\tau}^{-q} \Psi (x, q, -\infty, 0, \tau) \right) d\tau \]

\[ - _0^d_t d_{t}^{-q} \Psi (x, q, -\infty, 0, t). \]  

As evidenced by Equation 3.35, the \((-q)^{th}\) derivative of the psi-function can be considered a perturbation to the associated state [46].

The use of the Hankel operator also properly accounts for the initialization of a system. The Hankel operator accomplishes this for the fractional-order system as a whole, rather than on each individual fractional-order derivative like the psi-
function. However, both approaches do properly account for the past behavior of the fractional-order system in the future response.

3.7 Examples

We now consider two systems that include the semi-infinite line. Because of these inclusions, the systems are of fractional order.

3.7.1 Resistor-Terminated Semi-Infinite Line Example

Consider a resistor-terminated semi-infinite line, whose circuit diagram is given in Figure 3.1. This system has a transfer function $G_R(s)$ given by

$$G_R(s) = \frac{V_o(s)}{V_i(s)} = \frac{A}{s^2} \frac{1}{R + \frac{A}{s^2}} = \frac{\frac{A}{R}}{s^2 + \frac{A}{R}}. \tag{3.39}$$

The differential equation associated with this system is

$$-\infty d_t^\frac{3}{2} x(t) + \frac{A}{R} x(t) = \frac{A}{R} f(t).$$
The impulse response \( \tilde{g}_R(t) \) can be written using either the \( F \)-function approach as

\[
\tilde{g}_R(t) = \frac{A}{R} F_{\frac{1}{2}} \left( -\frac{A}{R}, t \right) = \frac{A}{R} \sum_{k=0}^{\infty} \left( -\frac{A}{R} \right)^{k-\frac{1}{2}} \frac{t^{k-\frac{1}{2}}}{\Gamma \left( \frac{k+\frac{1}{2}}{2} \right)}
\]

or using the approach of Miller and Ross [58] as

\[
\tilde{g}_R(t) = \frac{A}{R} \sum_{k=1}^{2} \left( -\frac{A}{R} \right)^{k-1} E_t \left( \frac{k-2}{2}, \left( -\frac{A}{R} \right)^2 \right).
\]

Note that \( G_R \left( |s| e^{i \text{arg}(s)} \right) = G_R \left( |s| e^{i (\text{arg}(s) + 4\pi)} \right) \), so there are only two unique Riemann sheets. Every Riemann sheet is a copy of either the primary Riemann sheet, which is given by \( \{ s \in \mathbb{C} : \text{arg} \,(s) \in (-\pi, \pi) \} \), or the secondary Riemann sheet, which is given by \( \{ s \in \mathbb{C} : \text{arg} \,(s) \in (\pi, 3\pi) \} \). Also note that \( G_R(s) \) has a pole at \( s_p = (\frac{A}{R})^2 e^{i2\pi} \). Because \( \text{arg} \,(s_p) \not\in (-\pi, \pi) \), this pole is on the secondary Riemann sheet rather than the primary Riemann sheet. Because of this the system exhibits ultradamping; the system decays without oscillation quickly from its initial condition, but decays more slowly as time progresses [33]. Note that no matter the value of \( \frac{A}{R} \), \( \lim_{t \to 0^+} \tilde{g}_R(t) = \infty \). The instantaneous rate of decay at any time \( t \) increases as \( \frac{A}{R} \) increases. Figure 3.2 shows \( \tilde{g}_R(t) \) for \( \frac{A}{R} \in \{ \frac{1}{2}, 1, 2 \} \). The basic shape of the impulse response is the same.

Consider the magnitude and phase plots of \( G_R(i\omega) \). At low frequencies \( \omega \ll \left( \frac{A}{R} \right)^2 \), the magnitude is approximately 0dB. At high frequencies \( \omega \gg \left( \frac{A}{R} \right)^2 \), the magnitude rolls off at 10\,\text{dB}\,\text{dec}^{-1}. The phase of \( G_R(i\omega) \) for high frequencies is \(-45^\circ\). For high frequencies, the phase of an integer-order system is an integer multiple of
Figure 3.2: Impulse Response for Resistor-Terminated Semi-Infinite Line with $\frac{A}{R} = \frac{1}{2}$ (dotted), $\frac{A}{R} = 1$ (dashed), and $\frac{A}{R} = 2$ (solid).

90°. At high frequencies the phase difference between $G_R(i\omega)$ and an integer-order approximation will be at least 45°. Figure 3.3 shows the magnitude and phase plots of $G_R(i\omega)$ with $\frac{A}{R} = 1$. Increasing $\frac{A}{R}$ increases the bandwidth of the system.

For the remainder of this document, we will consider the case where $\frac{A}{R} = 1$. Using the approximation

$$s^{-\frac{1}{2}} = \frac{13.39s^4 + 470.4s^3 + 1501s^2 + 470.4s + 13.39}{s^5 + 111.1s^4 + 1122s^3 + 1122s^2 + 111.1s + 1} \quad (3.40)$$
The magnitude and phase plots of this fifth-order approximation are shown in Figure 3.3. The approximation is good in magnitude for $10^{-2} < \omega < 10^2$ and good in phase for $10^{-2} < \omega < 10^1$. 

Figure 3.3: Magnitude and Phase Responses for a Resistor-Terminated Semi-Infinite Line with $\frac{A}{\pi} = 1$ (solid) and a Fifth-Order Approximation (dashed).
3.7.2 Inductor-Terminated Semi-Infinite Line

Another example is the inductor-terminated semi-infinite line. This problem, which has its roots in transatlantic communication in the late nineteenth century, was studied by Heaviside [36] and Bush [14]. The system is shown in Figure 3.4.

The transfer function for this system is

\[
G_L(s) = \frac{V_o(s)}{V_i(s)} = \frac{\frac{A}{s^2}}{sL + \frac{A}{s^2}} = \frac{\frac{A}{L}}{s^2 + \frac{A}{L}}.
\]

(3.42)

The differential equation for this system is

\[
-\infty d^2 \frac{\partial}{\partial t^2} x(t) + \frac{A}{L} x(t) = \frac{A}{L} f(t).
\]

Using the \(F\)-function approach, the impulse response for this system is

\[
\tilde{g}_L(t) = \frac{A}{L} F_{\frac{A}{L}} \left( -\frac{A}{L}, t \right) = \frac{A}{L} \sum_{k=0}^{\infty} \left( -\frac{A}{L} \right)^k \frac{t^{\frac{3k+1}{2}}}{\Gamma \left( \frac{3k+3}{2} \right)}.
\]

45
Note that $G_L \left( |s| e^{i\arg(s)} \right) = G_L \left( |s| e^{i\arg(s) + 4\pi} \right)$, so there are only two unique Riemann sheets. Also note that $G_L(s)$ has poles at $s_1 = \left( \frac{A}{L} \right)^\frac{2}{3} e^{i2\pi}$ and $s_{2,3} = \left( \frac{A}{L} \right)^\frac{2}{3} e^{\pm i\frac{2}{3}\pi}$. Because $\arg(s_1) \not\in (-\pi, \pi)$, this pole is on the secondary Riemann sheet rather than the primary Riemann sheet. The poles $s_{2,3}$ are in the left-half plane of the primary Riemann sheet. The contribution of $s_1$ to the impulse response rapidly decays without oscillation. As $\frac{A}{L}$ increases, the rate of decay increases. The contribution of $s_{2,3}$ to the impulse response is a decaying sinusoid, as would be expected from an integer-order system with complex conjugate poles in the left-half plane. The contribution from $s_{2,3}$ dominates the response. The effects on the amplitude, overshoot, settling time, and natural frequency of contribution from $s_{2,3}$ of changing $\frac{A}{L}$ are the same as changing an integer-order system with poles at $s_{2,3}$.

Figure 3.5 shows $\tilde{g}_L(t)$ for $\frac{A}{L} \in \{\frac{1}{2}, 1, 2\}$. The basic shape of the impulse response is the same. The amplitude and speed of the impulse response increase as $\frac{A}{L}$ increases. At low frequencies $\omega << \left( \frac{A}{L} \right)^\frac{2}{3}$, the magnitude is approximately 0dB. The magnitude response has a resonance at $\omega = \left( \frac{A}{L} \right)^\frac{2}{3}$ contributed by the poles $s_{2,3}$. At high frequencies $\omega << \left( \frac{A}{L} \right)^\frac{2}{3}$, the magnitude rolls off at 30\text{dB}/\text{dec}. The phase of $G_L(i\omega)$ for high frequencies is 135°. For high frequencies, the phase of an integer-order system is an integer multiple of 90°. At high frequencies the phase difference between $G_L(i\omega)$ and an integer-order approximation will be at least 45°. Figure 3.6 shows the magnitude and phase plots of $G_L(i\omega)$ for $\frac{A}{L} = 1$. 

46
Figure 3.5: Impulse Response for Inductor-Terminated Semi-Infinite Line with $\frac{A}{L} = \frac{1}{2}$ (dotted), $\frac{A}{L} = 1$ (dashed), and $\frac{A}{L} = 2$ (solid).

For the remainder of this document, we will consider the case where $\frac{A}{L} = 1$.

$G_L(s)$ can be approximated using Equation 3.40 by

$$
\hat{G}_L(s) = \frac{1}{s^{\frac{A}{L} + 111.1s^4 + 1122s^3 + 1122s^2 + 111.1s + 1} + 1 + 13.39s^4 + 470.4s^3 + 1501s^2 + 470.4s + 13.39} = \frac{13.39s^4 + 470.4s^3 + 1501s^2 + 470.4s + 13.39}{s^6 + 111.1s^5 + 1135.39s^4 + 1592.4s^3 + 1612.1s^2 + 471.4s + 13.39}.
$$

(3.43)
This sixth-order approximation is shown in Figure 3.6. The approximation is good in magnitude for $10^{-2} \leq \omega \leq 10^2$ and good in phase for $10^{-2} \leq \omega \leq 10^1$.

### 3.8 Conclusions

In this chapter the concepts of derivatives and systems of integer order have been extended to those of non-integer order. Non-integer order differintegrals have been defined, and fractional-order systems have been represented as differential equations, transfer functions, and convolution operators. A method by which fractional-order
systems may be approximated has been presented. We have discussed the complexity in finding an initial-condition response which properly accounts for the past behavior of the system in the future response. Finally, two examples illustrating these concepts have been considered. We now examine complex-order systems in more depth.
CHAPTER IV

CONJUGATE-ORDER OPERATORS

The fractional-order operator has been generalized to the complex-order operator [44, 54, 69]. Conjugate-order operators are operators where both a differintegral of complex order \( q \in \mathbb{C} \) and a differintegral of complex-conjugate order \( \bar{q} \) are present[6].

In this chapter we consider conjugate-order differintegrals and conjugate-order systems of the form \( G(s) = \frac{r}{s^q - a} + \frac{r}{s^{\bar{q}} - \bar{a}} \). We show that such systems have real-valued impulse responses and, if \( \text{Re}(q) \neq 0 \), have a finite number of poles on the primary Riemann sheet. For a fixed \( a \in \mathbb{C} \) we describe the set of \( q \in \mathbb{C} \) such that \( G(s) \) corresponds to a stable, causal system. Finally, for a fixed \( q \in \mathbb{C} \) we describe the set of \( a \in \mathbb{C} \) such that \( G(s) \) corresponds to a stable, causal system.

4.1 Complex-Order Differintegrals

In general, the complex-order differintegral acting on a function \( f(t) \) is defined as

\[
-\infty d_t^{-q} f(t) = -\infty d_t^{-(u+iv)} f(t),
\]  

(4.1)
for \( q = u + iv \). Let \( G(s) \) be the Laplace-domain representation of this complex-order differintegral operator. \( G(s) \) is given by

\[
G(s)F(s) = \mathcal{L}\left\{ \int_{-\infty}^{t} t^{q} f(t) \right\} = s^{-(u+iv)}F(s) = s^{-u}s^{-iv}F(s) = s^{-u}e^{-iv\ln(s)}F(s),
\]

(4.2)

so \( G(s) = s^{-u}e^{-iv\ln(s)} \). Using the Laplace transform pair,

\[
\mathcal{L}\left\{ s^{-q} \right\} = \frac{t^{q-1}}{\Gamma(q)},
\]

the impulse response \( \tilde{g}(t) \) of the system is found to be

\[
\tilde{g}(t) = \mathcal{L}^{-1}\{G(s)\} = \mathcal{L}^{-1}\{s^{-(u+iv)}\} = \frac{t^{u-iv-1}}{\Gamma(u + iv)}
\]

\[
= \frac{t^{u-1}}{\Gamma(u + iv)} e^{iv\ln(t)}.
\]

(4.3)

Using Euler’s identity, this can be written as

\[
\tilde{g}(t) = \mathcal{L}^{-1}\{G(s)\} = \frac{t^{u-1}}{\Gamma(u + iv)} (\cos(v \ln(t)) + i \sin(v \ln(t))).
\]

(4.4)

This impulse response is complex-valued for \( v \neq 0 \). However, it is seen in the next section that the complex-order differintegral plus its conjugate-order differintegral has a real-valued impulse response.
4.2 Conjugate-Order Differintegrals

We now define the conjugated differintegral as

\[-\infty d_t^{-u,v} f(t) = -\infty d_t^{-u+iv} f(t) + -\infty d_t^{-u-iv} f(t).\]  \hspace{1cm} (4.5)

The Laplace transform of Equation 4.5

\[\mathcal{L}\{ -\infty d_t^{-u,v} f(t) \} = (s^{-u+iv} + s^{-u-iv}) F(s) = s^{-u} (s^{iv} + s^{-iv}) F(s),\]

which after application of Euler’s identity gives

\[\mathcal{L}\{ -\infty d_t^{-u,v} f(t) \} = s^{-u} (e^{iv \ln(s)} + e^{-iv \ln(s)}) F(s) = s^{-u} ((\cos(v \ln(s)) + i \sin(v \ln(s)))
\]
\[+ (\cos(v \ln(s)) - i \sin(v \ln(s)))) F(s) = 2s^{-u} \cos(v \ln(s)) F(s).\]  \hspace{1cm} (4.6)

Hence, the Laplace-domain representation of the conjugated differintegral is \(G(s) = (s^{-u+iv} + s^{-u-iv}) = 2s^{-u} \cos(v \ln(s))\). The impulse response \(\tilde{g}(t)\) of this system is given by

\[\tilde{g}(t) = \mathcal{L}^{-1}\{G(s)\} = \mathcal{L}^{-1}\{s^{-u+iv} + s^{-u-iv}\} = \frac{t^{u+iv-1}}{\Gamma(u+iv)} + \frac{t^{u-iv-1}}{\Gamma(u-iv)}.\]  \hspace{1cm} (4.7)
Note that by [1],
\[ \text{Re} \left( \Gamma (u + iv) \right) = \text{Re} \left( \Gamma (u - iv) \right) \]
and
\[ \text{Im} \left( \Gamma (u + iv) \right) = -\text{Im} \left( \Gamma (u - iv) \right). \]
Hence, \( \tilde{g}(t) \) can be written as
\[
\tilde{g}(t) = t^{u-1} \left( \text{Re} \left( \frac{1}{\Gamma(u + iv)} \right) t^{iv} + i\text{Im} \left( \frac{1}{\Gamma(u + iv)} \right) t^{iv} \right.
+ \text{Re} \left( \frac{1}{\Gamma(u + iv)} \right) t^{-iv} - i\text{Im} \left( \frac{1}{\Gamma(u + iv)} \right) t^{-iv}\right)
= t^{u-1} \left( \text{Re} \left( \frac{1}{\Gamma(u + iv)} \right) (t^{iv} + t^{-iv}) + i\text{Im} \left( \frac{1}{\Gamma(u + iv)} \right) (t^{iv} - t^{-iv}) \right).
\]
We now write \( t^{\pm iv} = e^{\pm iv \ln(t)} \) and apply Euler’s identity to give
\[
\tilde{g}(t) = t^{u-1} \text{Re} \left( \frac{1}{\Gamma(u + iv)} \right) \left( \cos(v \ln(t)) + i \sin(v \ln(t)) \right)
+ t^{u-1} \text{Re} \left( \frac{1}{\Gamma(u + iv)} \right) \left( \cos(v \ln(t)) - i \sin(v \ln(t)) \right)
+ it^{u-1} \text{Im} \left( \frac{1}{\Gamma(u + iv)} \right) \left( \cos(v \ln(t)) + i \sin(v \ln(t)) \right)
- it^{u-1} \text{Im} \left( \frac{1}{\Gamma(u + iv)} \right) \left( \cos(v \ln(t)) - i \sin(v \ln(t)) \right). \quad (4.8)
\]
Hence, $\hat{g}(t)$ is given by

$$
\hat{g}(t) = \mathcal{L}^{-1}\left\{s^{-(u+iv)} + s^{-(u-iv)}\right\} = \mathcal{L}^{-1}\left\{2s^{-u}\cos(v \ln(s))\right\}
= 2t^{u-1}\left(\Re\left(\frac{1}{\Gamma(u+iv)}\right)\cos(v \ln(t)) - \Im\left(\frac{1}{\Gamma(u+iv)}\right)\sin(v \ln(t))\right).
$$

(4.9)

Note that this impulse response is a purely real-valued function [7].

Hence, when a complex-order operator is properly paired with its conjugate-order operator, a real-valued impulse response is created. This is analogous to a complex pole of an integer-order system. A system whose transfer function has a single complex pole has a complex-valued impulse response, but a system whose transfer function has two complex-conjugate poles has a real-valued impulse response.

### 4.3 Conjugate-Order Systems

Since conjugate-order differintegrals can produce systems with real-valued impulse responses, it is sensible to apply the same sort of process to more general operators of complex order. Hartley and Lorenzo [33] demonstrated the Laplace transform pair

$$
\mathcal{L}\{F_q(a, t)\} = \frac{1}{s^q - a},
$$

(4.10)

where $F_q(a, t)$ is the $F$-function as described in Section 3.4.3. The derivation of the Laplace transform pair does not require that $q$ or $a$ be real-valued. Consider the
system whose transfer function, \( G(s) \), is given by

\[
G(s) = \frac{r}{s^q - a} + \frac{\tau}{s^{\eta} - \alpha} = \frac{rs^q + \tau s^\eta - (\tau a + r\alpha)}{(s^q - a)(s^\eta - \alpha)}.
\]  

(4.11)

Using the Laplace transform pair given in Equation 4.10, the impulse response \( \hat{g}(t) \) of the system with transfer function \( G(s) \) is

\[
\hat{g}(t) = \mathcal{L}^{-1}\{G(s)\} = rF_q(a, t) + \tau F_\eta(\alpha, t).
\]  

(4.12)

For \( a, z \in \mathbb{C} \) and \( n \in \mathbb{N} \), recall that \( \overline{a^z} = (\overline{a})^n \) and \( \overline{\Gamma(z)} = \Gamma(\overline{z}) \). Hence, \( \hat{g}(t) \) may be written as

\[
\hat{g}(t) = r \sum_{n=0}^{\infty} \frac{a^n t^{(n+1)q}}{\Gamma((n+1)q)} + \tau \sum_{n=0}^{\infty} \frac{\overline{a^n t^{(n+1)\eta}}}{\Gamma((n+1)\eta)}
\]

\[
= \sum_{n=0}^{\infty} \left( r \frac{a^n}{\Gamma((n+1)q)} t^{(n+1)(u+iv)} + \tau \frac{\overline{a^n}}{\Gamma((n+1)\eta)} t^{(n+1)(u-iv)} \right)
\]

\[
= \sum_{n=0}^{\infty} t^{(n+1)u-1} \left( \Phi_n t^{(n+1)v} + \overline{\Phi_n} t^{-(n+1)v} \right),
\]  

(4.13)

where

\[
\Phi_n = \frac{ra^n}{\Gamma((n+1)q)}.
\]

This can be written as

\[
\hat{g}(t) = 2 \sum_{n=0}^{\infty} t^{(n+1)u-1} \left( \text{Re}(\Phi_n) \cos((n+1)v \ln(t)) + \text{Im}(\Phi_n) \sin((n+1)v \ln(t)) \right),
\]  

(4.14)
which is a real-valued time function. Hence, the convolution operator associated with the transfer function in Equation 4.11 maps real-valued functions to real-valued functions. We call the system associated with Equation 4.11 the fundamental linear conjugate-order system. We now state this result formally.

**Theorem 4.3.1** *The system with transfer function*

\[
G(s) = \frac{r}{s^a - a} + \frac{\bar{r}}{s^\bar{a} - \bar{a}}
\]

*has a real-valued impulse response.*

**Proof** See above. ■

4.3.1 Poles of the Fundamental Linear Conjugate-Order System

In order to gain an understanding of the system, it is desirable to find the poles of the system. Let \( x \) and \( y \) be given by

\[
x = \frac{u}{u^2 + v^2}
\]

and

\[
y = \frac{v}{u^2 + v^2}.
\]

Then

\[
\frac{1}{u \pm iv} = x \mp iy.
\]
The poles of $G(s)$ are given by

$$s = a^{\frac{1}{n+\nu}} = a^{x-iy} \quad (4.15)$$

and

$$s = (\bar{a})^{\frac{1}{n-\nu}} = (\bar{a})^{x+iy}. \quad (4.16)$$

First, consider the roots given by Equation 4.15. Note that $a$ can be written as

$$a = |a|e^{i\text{Arg}(a)+2\pi k} = e^{\ln|a|+i(\text{Arg}(a)+2\pi k)}$$

and $\bar{a}$ as

$$\bar{a} = |a|e^{-i(\text{Arg}(a)+2\pi k)} = e^{\ln|a|-i(\text{Arg}(a)+2\pi k)}.$$

Substituting $a$ into Equation 4.15 results in

$$s = (e^{\ln|a|+i(\text{Arg}(a)+2\pi k)})^{x-iy} = e^{x\ln|a|+y\text{Arg}(a)+y2\pi k}e^{i(x\text{Arg}(a)+x2\pi k+y\ln|a|)} \quad (4.17)$$

Similarly, substituting $\bar{a}$ into Equation 4.16 results in

$$s = (e^{\ln|a|-i(\text{Arg}(a)+2\pi k)})^{x+iy} = e^{x\ln|a|+y\text{Arg}(a)+y2\pi k}e^{-i(x\text{Arg}(a)+x2\pi k-y\ln|a|)} \quad (4.18)$$

which gives the complex conjugates of the poles given by Equation 4.17.
We consider now the poles that lie on the primary Riemann sheet, which are those whose angles lie between $-\pi$ and $\pi$. This means that

$$-\pi < x \text{Arg}(a) + x2\pi k - y \ln |a| < \pi.$$ 

**Theorem 4.3.2** If $\text{Re}(q) \neq 0$, then $G(s) = \frac{x}{s^2-a} + \frac{r}{s^2+q}$ has a finite number of poles on the primary Riemann sheet.

**Proof** Since the poles of $\frac{r}{s^2-a}$ are the complex conjugates of the poles of $\frac{r}{s^2-a}$, it suffices to show that $\frac{r}{s^2-a}$ has a finite number of poles on the primary Riemann sheet.

Consider $s_k$ a pole of $\frac{r}{s^2-a}$ which is given by Equation 4.18 as

$$s_k = \left| s_k \right| e^{i \text{Arg}(s_k)} = e^{x \ln |a| + y \text{Arg}(a) + x2\pi k} e^{i(x \text{Arg}(a) + x2\pi k - y \ln |a|)}.$$  (4.19)

Thus $s_k$ is on the primary Riemann sheet if and only if

$$\frac{y \ln |a| - x \text{Arg}(a) - \pi}{2\pi} < k < \frac{y \ln |a| - x \text{Arg}(a) + \pi}{2\pi}.$$  (4.20)

For $u = \text{Re}(q) \neq 0$, $x \neq 0$, so the requirement given in Equation 4.20 can be written as

$$\frac{y \ln |a| - x \text{Arg}(a) - \pi}{x2\pi} < k < \frac{y \ln |a| - x \text{Arg}(a) + \pi}{x2\pi}.$$  (4.21)

If there is no $k$ that satisfies Equation 4.21, then $G(s)$ has no poles on the primary Riemann sheet. If there is a $k$ that satisfies Equation 4.21, then $k$ is an element of an
open bounded interval. Therefore there are a finite number of integers \( k \) such that \( s_k \) is on the primary Riemann sheet.

We will now consider the conditions under which a conjugate-order system is stable and causal.

4.4 Stable, Causal Conjugate-Order Systems

We will show in Section 5.5.2 that a transfer function corresponds to a stable, causal system when it is analytic in the right-half plane of the primary Riemann sheet. The only singularities that the fundamental linear conjugate-order system can have in the right-half plane of the primary Riemann sheet are poles. Hence, we will say that the transfer function of the fundamental linear conjugate-order system is analytic in the right half plane of he primary Riemann sheet if it has no poles there. We now consider how many poles such a transfer function may have on the primary Riemann sheet.

**Theorem 4.4.1** If \( \text{Re} (q) \neq 0 \) and \( G(s) = \frac{r}{s^q - a} + \frac{s}{s^q - a} \) is analytic in the right half plane of the primary Riemann sheet, then \( G(s) \) has at most four poles on the primary Riemann sheet.

**Proof** Since the poles of \( \frac{r}{s^q - a} \) are the complex conjugates of the poles of \( \frac{s}{s^q - a} \), it suffices to show that \( \frac{r}{s^q - a} \) has at most two poles on the primary Riemann sheet.
Consider $s_k$ as given in Equation 4.19. The argument of $s_k$, given by

$$\arg (s_k) = x \text{Arg} (a) + x2\pi k - y \ln |a|, \quad (4.22)$$

is linear in $k$. Thus, by Equation 4.22, $|\arg (s_{k+1}) - \arg (s_k)|$ is constant, i.e.

$$|\arg (s_{k+1}) - \arg (s_k)| = |x| \cdot 2\pi. \quad (4.23)$$

Because $G(s)$ is assumed to be analytic in the right half plane of the primary Riemann sheet, there is no value of $k$ for which $-\frac{\pi}{2} < \arg (s_k) < \frac{\pi}{2}$. Therefore,

$$|\arg (s_{k+1}) - \arg (s_k)| > \pi \quad (4.24)$$

for any $k \in \mathbb{Z}$. Suppose that there are $M$ poles of $\frac{x}{s^q - a}$, on the primary Riemann sheet. This means that

$$|\arg (s_{k+M}) - \arg (s_k)| < 2\pi.$$

However, for a stable system, Equation 4.24 gives

$$|\arg (s_{k+M}) - \arg (s_k)| = \sum_{m=1}^{M-1} |\arg (s_{m+1}) - \arg (s_m)| > \sum_{m=1}^{M-1} \pi = (M - 1) \pi.$$

Thus,

$$(M - 1) \pi < |\arg (s_{k+M}) - \arg (s_k)| < 2\pi,$$
which implies

$$(M - 1) < 2$$

or

$$M < 3.$$ 

Thus if $\frac{r}{s^2-a}$ is stable, it has at most two poles on the primary Riemann sheet. Since the poles of $\frac{r}{s^2-a}$ are the complex conjugates of the poles of $\frac{r}{s^2-a}, \frac{r}{s^2-a} + \frac{r}{s^2-a}$ has at most four poles on the primary Riemann sheet. 

Corollary 4.4.2 Let $q \in \mathbb{C} \setminus \{0\}, G(s) = \frac{r}{s^2-a} + \frac{r}{s^2-a}, u = \text{Re}(q),$ and $v = \text{Im}(q).$

A necessary condition for $G(s)$ to be stable and causal is that $q = u + iv$ must satisfy either

$$u = 0, \hspace{1cm} (4.25)$$

$$(u - 1)^2 + v^2 < 1, \hspace{1cm} (4.26)$$

or

$$(u + 1)^2 + v^2 < 1. \hspace{1cm} (4.27)$$

Proof Suppose that $u \neq 0$. By Equation 4.23 and Equation 4.24 if $u \neq 0$ and $G(s)$ is stable, $2|x| > 1$. Thus, either $2x > 1$ or $-2x > 1$. Since $x = \frac{u}{u^2+v^2}, q = u + iv$ satisfies either

$$u^2 + v^2 < 2u \hspace{1cm} (4.28)$$
or
\[ u^2 + v^2 < -2u. \] (4.29)

Completing the square on both Equations 4.28 and 4.29 gives the desired result.  

4.4.1 Stable, Causal $G(s)$ for a Fixed $a$

Next we derive necessary and sufficient conditions for $G(s) = \frac{r}{s^2-a} + \frac{r}{s^2-a}$ to correspond to a stable, causal system.

**Theorem 4.4.3** For $q \in \mathbb{C} \setminus \{0\}$, $u = \text{Re} (q)$, $v = \text{Im} (q)$, and $a \in \mathbb{C}$, define

\[ u_k(a) = \frac{\text{Arg} (a) + 2\pi k}{\pi}, \]
\[ v_k(a) = \frac{\ln |a|}{\pi}, \]

\[ D^+_k(a) = \{ u + iv \in \mathbb{C} : (u - u_k)^2 + (v + v_k)^2 < u_k^2 + v_k^2 \}, \]

and

\[ D^-_k(a) = \{ u + iv \in \mathbb{C} : (u + u_k)^2 + (v - v_k)^2 < u_k^2 + v_k^2 \}. \]

Then $G(s) = \frac{r}{s^2-a} + \frac{r}{s^2-a}$ corresponds to a stable, causal system if and only if

\[ q \in \bigcap_{k \in \mathbb{Z}} \left( D^+_k(a) \cup D^-_k(a) \right). \]
Proof Recall that the poles of $\frac{r}{s^{r-a}}$ are the complex-conjugates of the poles of $\frac{r}{s^{r-a}}$, so we only need to consider the poles \{s_k\} of $\frac{r}{s^{r-a}}$. The argument of $s_k$ is given by Equation 4.22 as

$$\arg(s_k) = x \text{Arg}(a) + x 2\pi k - y \ln|a|$$

$$= \frac{u \text{Arg}(a) + u 2\pi k - y \ln|a|}{u^2 + v^2}.$$

$G(s)$ corresponds to a stable, causal system if and only if the right-half plane on the primary Riemann sheet is analytic. That is, $G(s)$ corresponds to a stable, causal system if and only if for every $k \in \mathbb{Z}$, either

$$\frac{u \text{Arg}(a) + u 2\pi k - y \ln|a|}{u^2 + v^2} > \frac{\pi}{2}$$

(4.30)

or

$$\frac{u \text{Arg}(a) + u 2\pi k - y \ln|a|}{u^2 + v^2} < -\frac{\pi}{2}$$

(4.31)

holds. Multiplying both sides of the inequality in Equation 4.30 by $\frac{2}{\pi} (u^2 + v^2) > 0$ gives

$$2u \left( \frac{\text{Arg}(a) + 2\pi k}{\pi} - 2v \frac{\ln|a|}{\pi} \right) - 2v \frac{\ln|a|}{\pi} > u^2 + v^2.$$  

Bringing each term to the right of the inequality gives

$$0 > u^2 - 2u \frac{\text{Arg}(a) + 2\pi k}{\pi} + v^2 + 2v \frac{\ln|a|}{\pi}.$$
Completing the square for both $u$ and $v$ gives

\[
\begin{align*}
    u^2 &= 2u \frac{\text{Arg}(a) + 2\pi k}{\pi} + \left( \frac{\text{Arg}(a) + 2\pi k}{\pi} \right)^2 + v^2 + 2v \frac{\ln |a|}{\pi} + \left( \frac{\ln |a|}{\pi} \right)^2 \\
    &< \left( \frac{\ln |a|}{\pi} \right)^2 + \left( \frac{\text{Arg}(a) + 2\pi k}{\pi} \right)^2,
\end{align*}
\]

which simplifies to

\[
\left( u - \frac{\text{Arg}(a) + 2\pi k}{\pi} \right)^2 + \left( v + \frac{\ln |a|}{\pi} \right)^2 < \left( \frac{\text{Arg}(a) + 2\pi k}{\pi} \right)^2 + \left( \frac{\ln |a|}{\pi} \right)^2. \tag{4.32}
\]

Considering this relation in the $(u, v)$ plane, this gives an open disk centered at

\[
\frac{\text{Arg}(a) + 2\pi k}{\pi} - i \frac{\ln |a|}{\pi} = u_k - iv_k,
\]

with radius, $\rho_k$, given by

\[
\rho_k = \sqrt{\left( \frac{\text{Arg}(a) + 2\pi k}{\pi} \right)^2 + \left( \frac{\ln |a|}{\pi} \right)^2} = |u_k + iv_k|.
\]

The set of $q \in \mathbb{C}$ that satisfy Equation 4.32 for a specific $k \in \mathbb{Z}$ is the set of $q$ such that $q \in D_k^+(a)$.

Similarly, Equation 4.31 can be written as

\[
\left( u + \frac{\text{Arg}(a) + 2\pi k}{\pi} \right)^2 + \left( v - \frac{\ln |a|}{\pi} \right)^2 < \left( \frac{\text{Arg}(a) + 2\pi k}{\pi} \right)^2 + \left( \frac{\ln |a|}{\pi} \right)^2,
\]
which is an open disk centered at

$$- \frac{\text{Arg}(a) + 2\pi k}{\pi} + \frac{i \ln|a|}{\pi} = -u_k + iv_k,$$

with radius, $\rho_k$, given by

$$\rho_k = \frac{\sqrt{(\text{Arg}(a) + 2\pi k)^2 + \ln^2|a|}}{\pi} = |u_k + iv_k|.$$

The set of $q \in \mathbb{C}$ that satisfy Equation 4.33 for a specific $k \in \mathbb{Z}$ is the set of $q$ such that $q \in D_k^-(a)$.

Given $a \in \mathbb{C}$, the set of $q$ such that $G(s)$ corresponds to a stable, causal system is $q \in Q$, where

$$Q = \bigcap_{k \in \mathbb{Z}} \left( D_k^+(a) \cup D_k^-(a) \right).$$

(4.33)

Note that if $|a| \neq 1$, then part of the imaginary axis is in the set $Q = \bigcap_{k \in \mathbb{Z}} \left( D_k^+(a) \cup D_k^-(a) \right)$. For such $a$, if the center of $D_k^+(a)$ is in the upper-right quarter plane, then a portion of $D_k^+(a)$ extends into the upper-left quarter plane and contains an interval on the imaginary axis. The smallest of these disks determines the length of that interval. As $k$ is varied to increase the size of $D_k^+(a)$, depth into which the disk enters the upper-left quarter plane decreases. For any point $s_0$ in the upper-left quarter plane, we may find a $k$ such that $D_k^+(a)$ whose center is in the upper-right quarter plane does not contain $s_0$. We can make a similar argument for
disks centered in the upper-left, lower-left, and lower-right quarter planes. For \( v \neq 0 \), there is a small \( u \) such that \( iv \in \mathcal{Q} \) but \( u + iv \not\in \mathcal{Q} \).

Note that in the notation of Theorem 4.4.3, Corollary 4.4.2 states that a necessary condition for \( q \in \mathbb{C} \) to correspond to a stable, causal system is that \( q \in \left( D^+_0(-1) \cup D^-_0(-1) \cup i\mathbb{R} \right) \). We now show that Theorem 4.4.3 does not contradict Corollary 4.4.2.

**Theorem 4.4.4** For \( q \in \mathbb{C} \setminus \{0\} \), \( u = \text{Re}(q) \), \( v = \text{Im}(q) \), and \( a \in \mathbb{C} \), define

\[
    u_k(a) = \frac{\text{Arg}(a) + 2\pi k}{\pi},
\]

\[
    v_k(a) = \frac{\ln|a|}{\pi},
\]

\[
    D^+_k(a) = \{ u + iv \in \mathbb{C} : (u - u_k)^2 + (v + v_k)^2 < u_k^2 + v_k^2 \},
\]

and

\[
    D^-_k(a) = \{ u + iv \in \mathbb{C} : (u + u_k)^2 + (v - v_k)^2 < u_k^2 + v_k^2 \}.
\]

Then

\[
    \bigcap_{k \in \mathbb{Z}} (D^+_k(a) \cup D^-_k(a)) \subset \left( D^+_0(-1) \cup D^-_0(-1) \cup i\mathbb{R} \right).
\]

**Proof** Suppose \( q \not\in \left( D^+_0(-1) \cup D^-_0(-1) \cup i\mathbb{R} \right) \). Then \(-\frac{1}{2} \leq \frac{u}{u^2 + v^2} \leq \frac{1}{2} \) and \( u \neq 0 \). If \( u > 0 \), then \( \frac{v^2 + u^2}{2u} \geq \frac{1}{2} \geq -\frac{v^2 + u^2}{2u} \). If \( u < 0 \), then \( \frac{v^2 + u^2}{2u} \leq -1 \leq -\frac{v^2 + u^2}{2u} \). Define \( m \) by

\[
    m = \frac{v \ln|a| - u \text{Arg}(a)}{\pi (u^2 + v^2)}.
\]
If $u > 0$, choose $k_0 \in \mathbb{Z}$ such that $\frac{m(u^2+v^2)}{2u} \leq k_0 \leq \frac{(m+1)(u^2+v^2)}{2u}$. Such a $k_0$ exists because
\[
\frac{(m+1)(u^2+v^2)}{2u} - \frac{m(u^2+v^2)}{2u} = \frac{u^2+v^2}{2u} > 1.
\]
If $u < 0$ choose $k_0 \in \mathbb{Z}$ such that
\[
\frac{(m+1)(u^2+v^2)}{2u} \leq k_0 \leq \frac{m(u^2+v^2)}{2u}.
\]
Such a $k_0$ exists because $\frac{m(u^2+v^2)}{2u} - \frac{(m+1)(u^2+v^2)}{2u} = \frac{u^2+v^2}{2u} < -1$. Hence there exists a $k_0 \in \mathbb{Z}$ such that
\[
m \leq \frac{2u}{u^2+v^2} k_0 \leq m + 1
\]
or
\[
\pi \left( m - \frac{1}{2} \right) \leq \frac{2\pi u}{u^2+v^2} k_0 + 0 \leq \pi \left( m + \frac{1}{2} \right).
\]
(4.34)

Rearranging Equation 4.34 gives
\[
-\frac{\pi}{2} \leq \frac{2\pi u k_0}{u^2+v^2} - m \leq \frac{\pi}{2},
\]
which can be rewritten as
\[
-\frac{\pi}{2} \leq \frac{u \text{Arg}(a) + u2\pi k_0 - v \ln|a|}{u^2+v^2} \leq \frac{\pi}{2}.
\]
Hence, there exists a $k_0 \in \mathbb{Z}$ such that $q = u + iv$ satisfies neither Equation 4.30 nor Equation 4.31. Thus, $q \not\in \left( D^+_k(a) \cup D^-_k(a) \right)$. Subsequently,
\[
\bigcap_{k \in \mathbb{Z}} \left( D^+_k(a) \cup D^-_k(a) \right) \subset \left( D^+_0(-1) \cup D^-_0(-1) \right).
\]

\[\blacksquare\]

67
None of the discussion in this section has considered the case where $q = 0$. In this case $G(s) = \frac{r}{1-a} + \frac{p}{1-\pi}$. For $a \neq 1$, $G(s)$ is a constant, and $G$ multiplies inputs by that constant. This is a stable system.

### 4.4.2 Examples

We now apply Theorem 4.4.3 to several examples. We show the set of $q \in \mathbb{C}$ for which $G(s) = \frac{r}{s^q-a} + \frac{p}{s^q-\pi}$ corresponds to a stable, causal system for a given $a \in \mathbb{C}$. In the figures to follow, the boundaries of $D_0^+(-1)$ and $D_0^-(1)$ are depicted with dashed lines. This is to show that universal boundary for $G(s)$ to correspond to a stable, causal system for $q \notin i\mathbb{R}$.

Figure 4.1 shows the region of $q \in \mathbb{C}$ such that $G(s) = \frac{r}{s^q+(e^{i\pi})} + \frac{p}{s^q-(e^{-i\pi})}$ corresponds to a stable causal system. For this system all $q$ such that $G(s)$ corresponds to a stable, causal system are in either $D_0^+(-1)$ or $D_0^-(1)$.

Figures 4.2, 4.3, 4.4, 4.5, 4.6, 4.7, 4.8, 4.9, 4.10, 4.11, 4.12, and 4.13 show the set of $q$ for which $G(s) = \frac{r}{s^q-(|a|e^{i\pi})} + \frac{p}{s^q-(|a|e^{-i\pi})}$ corresponds to a stable, causal system for $|a| = 2^{\pm k}$ for $1 \leq k \leq 12$. We will call the open set including part of the $v$-axis the primary lobe. We note several trends as $|a|$ differs more from unity. As $|a|$ gets farther from unity, the size of the primary lobe decreases. Also non-primary lobes appear and grow larger as $|a|$ varies from unity. We also note in these figures that for $|a| > 16$, we have not included a portion of the $v$-axis where $q$ admits a stable, causal $G(s)$ because we prefer to keep the scaling the same on each of the figures.
Figure 4.1: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^{\arg(a)}} + \frac{p}{s^{\arg(a)}}$ is stable and causal.

Figures 4.13, 4.13, 4.13, and 4.13 show the set of $q$ for which the transfer function $G(s) = \frac{r}{s^{\arg(a)}} + \frac{p}{s^{\arg(a)}}$ corresponds to a stable, causal system for $\arg(a) = \pi$, $\arg(a) = \frac{\pi}{2}$, $\arg(a) = 0$, and $\arg(a) = -\frac{\pi}{2}$, respectively. As the argument of $a$ decreases, the primary and other lobes seem to rotate in the $(u,v)$ plane.
Figure 4.2: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s\gamma-(2e^{i\pi})} + \frac{p}{s\gamma-(2e^{-i\pi})}$ is stable and causal.
Figure 4.3: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - (4e^{-\pi})} + \frac{r}{s^2 - (4e^{\pi})}$ is stable and causal.
Figure 4.4: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^{q}-(8e^{ix})} + \frac{r}{s^{q}-(8e^{-ix})}$ is stable and causal.
Figure 4.5: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - (16e^{i\pi})} + \frac{r}{s^2 - (16e^{-i\pi})}$ is stable and causal.
Figure 4.6: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - (32e^{i\pi})} + \frac{r}{s^2 - (32e^{-i\pi})}$ is stable and causal.
Figure 4.7: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - (64e^{i\pi})} + \frac{r}{s^2 - (64e^{-i\pi})}$ is stable and causal.
Figure 4.8: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - (128e^{iv})} + \frac{r}{s^2 - (128e^{-iv})}$ is stable and causal.
Figure 4.9: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - (256e^{iv})} + \frac{r}{s^2 - (256e^{-iv})}$ is stable and causal.
Figure 4.10: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^9 - (512e^{i\alpha})} + \frac{p}{s^9 - (512e^{-i\alpha})}$ is stable and causal.
Figure 4.11: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^9 - (1024e^{1\pi})} + \frac{r}{s^9 - (1024e^{-1\pi})}$ is stable and causal.
Figure 4.12: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^9 - (2048e^{10})} + \frac{r}{s^9 - (2048e^{-10})}$ is stable and causal.
Figure 4.13: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^9 - (4096e^{10}r)} + \frac{r}{s^9 - (4096e^{-10}r)}$ is stable and causal.
Figure 4.14: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - \left(4096e^{i\frac{\pi}{2}}\right)} + \frac{\tau}{s^2 - \left(4096e^{-i\frac{\pi}{2}}\right)}$ is stable and causal.
Figure 4.15: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^2 - (4096e^{-\alpha})} + \frac{p}{s^2 - (4096e^{-\alpha})}$ is stable and causal.
Figure 4.16: Set of $q = u + iv$ for which the system $G(s) = \frac{r}{s^\gamma(4096e^{-17})} + \frac{\rho}{s\tau(4096e^{17})}$ is stable and causal.
4.4.3 Stable, Causal $G(s)$ for a Fixed $q$

We now consider for a given $q \in \mathbb{C}\setminus \{0\}$ the set of $a$ for which $G(s) = \frac{r}{s^q-a} + \frac{r}{s^\pi-a}$ corresponds to a stable, causal system. It is easier to consider the set of $a$ for which $G(s)$ corresponds to an unstable or noncausal system. We also want to consider $a$ that are not on the primary Riemann sheet, so we look in the $(\ln |a|, \text{Arg} (a))$ plane rather than the $(\text{Re} (a), \text{Im} (a))$ plane.

**Theorem 4.4.5** For $q \in \mathbb{C}\setminus \{0\}$ with $u = \text{Re} (q)$ and $v = \text{Im} (q)$, $G(s) = \frac{r}{s^q-a} + \frac{r}{s^\pi-a}$ corresponds to an unstable or noncausal system if for $u = 0$

$$e^{-\frac{\pi}{2}|v|} \leq |a| \leq e^{\frac{\pi}{2}|v|},$$

(4.35)

or for $\beta = \frac{v}{u}$ with $u \neq 0$

$$\beta \ln |a| - 2\pi k - \frac{\pi}{2}(1 + \beta^2)|u| \leq \text{Arg} (a) \leq \beta \ln |a| - 2\pi k + \frac{\pi}{2}(1 + \beta^2)|u|,$$

(4.36)

any $k \in \mathbb{Z}$ with $u \neq 0$.

**Proof** Because the poles of $\frac{r}{s^q-a}$ are the complex conjugates of $\frac{r}{s^\pi-a}$, we may consider only the poles of $\frac{r}{s^q-a}$, which are given by Equation 4.19 as

$$s_k = e^{x \ln |a| + y \text{Arg} (a) + y 2\pi k} e^{i(x \text{Arg} (a) + x 2\pi k - y \ln |a|)}.$$
Then $G(s)$ is either unstable or noncausal if $-\frac{\pi}{2} \leq \arg(s) \leq \frac{\pi}{2}$. This can be written as

$$-\frac{\pi}{2}(u^2 + v^2) \leq u\arg(a) + u2\pi k - v\ln|a| \leq \frac{\pi}{2}(u^2 + v^2).$$  \hspace{1cm} (4.37)

We consider two cases, where $u = 0$ and where $u \neq 0$.

Suppose $u = 0$ and $v \neq 0$, then Equation 4.37 becomes

$$-\frac{\pi}{2}v^2 \leq v\ln|a| \leq \frac{\pi}{2}v^2.$$  \hspace{1cm} (4.38)

If $v > 0$, then dividing Equation 4.38 by $v$ gives

$$-\frac{\pi}{2}|v| \leq \ln|a| \leq \frac{\pi}{2}|v|.$$  \hspace{1cm} (4.39)

If $v < 0$, then dividing Equation 4.38 by $v$ gives

$$\frac{\pi}{2}|v| \geq \ln|a| \geq -\frac{\pi}{2}|v|,$$

which is the same as Equation 4.39. Hence, $|a|$ satisfies

$$e^{-\frac{\pi}{2}|v|} \leq |a| \leq e^{\frac{\pi}{2}|v|},$$

which is a vertical strip in the $(|a|, \arg(a))$ plane.
Suppose now that \( u \neq 0 \) and \( v = \beta v \). Then Equation 4.37 can be written as

\[
-\frac{\pi}{2}(1 + \beta^2 u^2) \leq u \arg(a) + u 2\pi k - \beta u \ln |a| \leq \frac{\pi}{2}(1 + \beta^2) u^2. \tag{4.40}
\]

If \( u > 0 \), then dividing Equation 4.40 by \( u \) gives

\[
-\frac{\pi}{2}(1 + \beta^2 |u|) \leq \arg(a) + 2\pi k - \beta \ln |a| \leq \frac{\pi}{2}(1 + \beta^2) |u|. \tag{4.41}
\]

Similarly if \( u < 0 \), then dividing Equation 4.40 by \( u \) gives

\[
\frac{\pi}{2}(1 + \beta^2 |u|) \geq \arg(a) + 2\pi k - \beta \ln |a| \geq -\frac{\pi}{2}(1 + \beta^2) |u|,
\]

which is the same as Equation 4.41. Isolating \( \arg(a) \) in Equation 4.41 gives

\[
\beta \ln |a| - 2\pi k - \frac{\pi}{2}(1 + \beta^2) |u| \leq \arg(a) \leq \beta \ln |a| - 2\pi k + \frac{\pi}{2}(1 + \beta^2) |u|, \tag{4.42}
\]

which is a curved strip in the \((|a|, \arg(a))\) plane for each \( k \in \mathbb{Z} \).

Note that if \( \beta = 0 \), which means that \( q \in \mathbb{R} \), then Equation 4.42 reduces to

\[
-\frac{\pi}{2} |u| \leq \arg(a) \leq \frac{\pi}{2} |u|,
\]

which is the result of [56]. We can now consider for which values of \( a \) the transfer function \( G(s) \) corresponds to a stable, causal system.
Corollary 4.4.6 For \( q \in \mathbb{C} \setminus \{0\} \) with \( u = \text{Re} (q) \) and \( v = \text{Im} (q) \), \( G(s) = \frac{r}{s^u - \alpha} + \frac{r}{s^v - \beta} \)

corresponds to a stable, causal system if

\[
|a| \not\in \left[ e^{-\frac{\pi}{2} |v|}, e^{\frac{\pi}{2} |v|} \right],
\] (4.43)

for \( u = 0 \) or

\[
\beta \ln |a| - 2\pi (k + 1) - \frac{\pi}{2} (1 + \beta^2) |u| \leq \text{Arg} (a) \leq \beta \ln |a| - 2\pi k + \frac{\pi}{2} (1 + \beta^2) |u|, \quad (4.44)
\]

for any \( k \in \mathbb{Z} \) with \( u \neq 0 \).

Proof We take the complement of the sets from Theorem 4.4.5.

4.4.4 Examples

Now we apply Corollary 4.4.6 to a variety of \( q = u + iv \) such that \((u - 1)^2 + v^2 < 1\).

Figures 4.17 through 4.23 show the effect on the set of stable \( a \) when \( \beta \) is held constant at unity and \( u \) is increased from \( \frac{1}{10} \) to \( \frac{99}{100} \). The band of stable \( a \) decreases as \( u \) increases, while the center of the bands are close to each other. Figure 4.23 is close to the case when \( u = 1 \) and \( \beta = 1 \). Figures 4.24 through 4.28 show the effects on the set of stable \( a \) when \( u \) is held constant at unity and \textit{beta} is decreased from \( \frac{4}{5} \) through 0. Figure 4.28 is the integer-order case, whose results are as expected.
Figure 4.17: Set of $a = |a|e^{i\text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^{\frac{1+i}{2}}-a} + \frac{r}{s^{\frac{1-i}{2}}-\pi}$ is stable and causal.
Figure 4.18: Set of $a = |a|e^{i\arg(a)}$ for which the system $G(s) = \frac{r}{s^{\frac{1}{2}(1+i)-a}} + \frac{r}{s^{\frac{1}{2}(1-i)-\pi}}$ is stable and causal.
Figure 4.19: Set of $a = |a|e^{i\text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^{\frac{3}{4}(1+i)-a}} + \frac{r}{s^{\frac{3}{4}(1-i)-\pi}}$ is stable and causal.
Figure 4.20: Set of $a = |a|e^{i\text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^{\frac{1}{2}(1+i)} - a} + \frac{r}{s^{\frac{1}{2}(1-i)} - \pi}$ is stable and causal.
Figure 4.21: Set of $a = |a|e^{i\text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^{\frac{1}{2}}(1+i) - a} + \frac{r}{s^{\frac{1}{2}}(1-i) - \pi}$ is stable and causal.
Figure 4.22: Set of $a = |a|e^{i\arg(a)}$ for which the system $G(s) = \frac{r}{s^{\frac{1}{2}(1+i)} - a} + \frac{r}{s^{\frac{1}{2}(1-i)} - \pi}$ is stable and causal.
Figure 4.23: Set of $a = |a|e^{i\text{arg}(a)}$ for which the system $G(s) = \frac{r}{s\theta(1+s) - a} + \frac{r}{\theta s\theta(1-s) - \pi}$ is stable and causal.
Figure 4.24: Set of $a = |a|e^{i\text{arg}(a)}$ for which the system $G(s) = \frac{r}{s^{(1+\frac{1}{2})-\alpha} - \alpha} + \frac{r}{s^{(1-\frac{1}{2})}-\pi}$ is stable and causal.
Figure 4.25: Set of $a = |a|e^{i\text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^{1+\frac{\text{Arg}(a)}{2}}-a} + \frac{r}{s^{1-\frac{\text{Arg}(a)}{2}}-\pi}$ is stable and causal.
Figure 4.26: Set of $a = |a|e^{i\text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^{(1+\frac{i}{5})}-a} + \frac{r}{s^{(1-\frac{i}{5})}-\pi}$ is stable and causal.
Figure 4.27: Set of $a = |a|e^{i\text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^{(1+\frac{1}{5})} - a} + \frac{r}{s^{(1-\frac{1}{5})} - \pi}$ is stable and causal.
Figure 4.28: Set of $a = |a| e^{i \text{Arg}(a)}$ for which the system $G(s) = \frac{r}{s^2 - a} + \frac{r}{s^2 - \bar{a}}$ is stable and causal.
4.5 Conclusions

In this chapter it has been demonstrated that pairs of complex-conjugate complex-order differintegrals map real-valued functions to real-valued functions. The fundamental, linear conjugate-order system
\[ \mathcal{A}(\mathbf{s}) = \mathbf{s}^q - a \mathbf{s}^{-q} + \mathbf{s}^{-q} - \mathbf{s}^q \]
has been introduced. \( \mathcal{A}(\mathbf{s}) \) maps real-valued functions to real-valued functions. The poles of \( \mathcal{A}(\mathbf{s}) \) have been determined, and the sets of \( q \) and \( a \) for which \( \mathcal{A}(\mathbf{s}) \) corresponds to a stable, causal system have been found. Numerous examples of such \( q \) for a fixed \( a \) and of such \( a \) for a fixed \( q \) have been given. Next, we discuss Hilbert spaces as an abstract setting in which we may consider fractional-order operators.
CHAPTER V
OPERATORS ON A HILBERT SPACE

We have demonstrated in Chapter 2 that integer-order, linear, time-invariant systems can be represented as convolution operators. In this chapter we provide a general and abstract framework in which convolution operators may be considered. To that end Hilbert spaces are introduced. Compact operators, those operators to which linear operators on finite-dimensional spaces can be generalized, are discussed. The most important result concerning compact operators is the Schmidt decomposition, which indicates that a compact operator can be fully described by a countable set of scalars, called singular values, and a countable set of basis-vector pairs for the domain and range of the operator, called Schmidt pairs. We then focus on the Hilbert space $L_2(\mathbb{R})$ and some isomorphisms of $L_2(\mathbb{R})$, specifically $L_2(i\mathbb{R}), L_2(\mathbb{T}),$ and $\ell_2(\mathbb{Z})$. Boundedness, compactness, and finite-rank criteria for integral operators on $L_2(\mathbb{R})$ are considered. This chapter closes with three methods by which the eigenvalues, and thus the singular values, of compact Hermitian operators may be evaluated. The first of these methods will be applied to the Hankel operators of fractional-order systems in Chapter 7.
5.1 Hilbert Spaces

We begin by defining norms and inner products, which allow us to define the geometry of the Hilbert space. We will let $\mathbb{F}$ denote either $\mathbb{C}$ or $\mathbb{R}$.

**Definition** Let $\mathcal{X}$ be a vector space over a field $\mathbb{F}$. A **norm** on $\mathcal{X}$ is a function $\| \cdot \| : \mathcal{X} \to \mathbb{R}$ such that for $\alpha \in \mathbb{F}$ and for $x, y \in \mathcal{X}$

1. $\|\alpha x\| = |\alpha| \|x\|$ and
2. $\|x + y\| \leq \|x\| + \|y\|$.

An **inner product** on $\mathcal{X}$ is a function $\langle \cdot, \cdot \rangle : \mathcal{X} \times \mathcal{X} \to \mathbb{F}$ such that for all $\alpha, \beta \in \mathbb{F}$ and for all $x, y, z \in \mathcal{X}$

1. $\langle x, y \rangle = \overline{\langle y, x \rangle}$
2. $\langle \alpha x + \beta y, z \rangle = \alpha \langle x, z \rangle + \beta \langle y, z \rangle$
3. $\langle x, x \rangle \in \mathbb{R}$ and $\langle x, x \rangle \geq 0$
4. $\langle x, x \rangle = 0$ if and only if $x = 0$.

For clarity, the space over which a norm or inner product is taken may be indicated by a subscript, for example $\| \cdot \|_{\mathcal{X}}$ or $\langle \cdot, \cdot \rangle_{\mathcal{X}}$. When it is clear which space is associated with the norm or inner product, the subscript will be omitted.

For any inner product $\langle \cdot, \cdot \rangle$, $\|x\| = (\langle x, x \rangle)^{\frac{1}{2}}$ is a norm. This norm is called the norm induced by the inner product. With the definitions of a norm and an inner product, a Hilbert space may be defined.
**Definition** A *Hilbert space* is a vector space $\mathcal{H}$ over a field $\mathbb{F}$ along with an inner product $\langle \cdot, \cdot \rangle$ such that, relative to the norm induced by the inner product, every Cauchy sequence in $\mathcal{H}$ converges to an element of $\mathcal{H}$. That is, a Hilbert space is a complete inner-product space.

**Theorem 5.1.1** Let $E \subset \mathbb{R}^n$ be measurable. $L_2(E)$, the space of all functions square-integrable on $E$, is a Hilbert space with $\langle f, g \rangle = \int_E fg$ for $f, g \in L_2(E)$.

**Proof** See [20].

Subsequently, we will use the fact that $\mathbb{R}$, $\mathbb{R}_+$, $\mathbb{R}_-$, $i\mathbb{R}$, and $\mathbb{T}$ are measurable to discuss operators on the Hilbert spaces $L_2(\mathbb{R})$, $L_2(\mathbb{R}_+)$, $L_2(\mathbb{R}_-)$, $L_2(i\mathbb{R})$, and $L_2(\mathbb{T})$.

One of the most useful concepts of a Hilbert space is the idea of orthogonality. Orthogonality describes the underlying geometric structure of a Hilbert space.

**Definition** Let $\mathcal{H}$ be a Hilbert space and let $f, g \in \mathcal{H}$. $f$ and $g$ are said to be *orthogonal* if $\langle f, g \rangle = 0$. $\{f_k\}$ is said to be an *orthogonal set* if $\langle f_m, f_n \rangle = 0$ whenever $m \neq n$. $\{f_k\}$ is said to be an *orthonormal set* if $\{f_k\}$ is an orthogonal set and if each member of $\{f_k\}$ has unity norm. A *basis* is a maximal orthonormal set.

One use of orthogonality is in the idea of an orthogonal complement, which will be used to decompose spaces into two orthogonal subspaces.

**Definition** Let $\mathcal{H}$ be a Hilbert space and let $E$ be a subspace of $\mathcal{H}$. The *orthogonal complement of $E$* is the set $E^\perp = \{g \in \mathcal{H} : \langle g, f \rangle = 0 \text{ for all } f \in E\}$.

The direct sum is a way of decomposing a given Hilbert space into component spaces, or building a larger Hilbert space from Hilbert spaces.
**Definition** Let $\mathcal{M}$ and $\mathcal{N}$ be subspaces of the Hilbert space $\mathcal{H}$. $\mathcal{H}$ is the *direct sum* of $\mathcal{M}$ and $\mathcal{N}$, denoted $\mathcal{H} = \mathcal{M} \oplus \mathcal{N}$, if $\mathcal{M} \cap \mathcal{N} = \{0\}$ and if every member of $\mathcal{H}$ can be expressed as the sum of a member of $\mathcal{M}$ with a member of $\mathcal{N}$. If $\langle m, n \rangle = 0$ for all $m \in \mathcal{M}$ and for all $n \in \mathcal{N}$, then $\mathcal{H}$ is said to be the *orthogonal direct sum* of $\mathcal{M}$ and $\mathcal{N}$ [87].

It is clear that if $\mathcal{H}$ is the orthogonal direct sum of $\mathcal{M}$ and $\mathcal{N}$, then $\mathcal{N} = \mathcal{M}^\perp$. The converse is also true.

**Theorem 5.1.2** If $\mathcal{M}$ is a subspace of a Hilbert space $\mathcal{H}$, then $\mathcal{H} = \mathcal{M} \oplus \mathcal{M}^\perp$; that is, $\mathcal{H}$ is the orthogonal direct sum of $\mathcal{M}$ and $\mathcal{M}^\perp$.

**Proof** See [20].

We use this result in Section 5.5 to obtain a decomposition of $L_2(\mathbb{T})$.

We next define a map that preserves the basic structure of the Hilbert space.

**Definition** Let $\mathcal{H}$ and $\mathcal{N}$ be Hilbert spaces. An *isomorphism* between $\mathcal{H}$ and $\mathcal{N}$ is a linear surjection $U : \mathcal{H} \to \mathcal{N}$ such that

$$\langle Uh, Ug \rangle_{\mathcal{N}} = \langle h, g \rangle_{\mathcal{H}}$$

for all $g, h \in \mathcal{H}$. $\mathcal{H}$ and $\mathcal{N}$ are said to be *isomorphic*, which is denoted $\mathcal{H} \cong \mathcal{N}$.

It can be shown that being isomorphic is an equivalence relation for Hilbert spaces [20]. This is justified because the inner product describes the essential relationship between members of the Hilbert space. Since the relationship between two
members of $\mathcal{H}$ is the same as that between the corresponding members of $\mathcal{N}$, $\mathcal{H}$ and $\mathcal{N}$ can be considered the same as each other.

5.2 Bounded Operators

We now discuss linear operators on a Hilbert space, paying particular attention to bounded operators which play an important role in system theory because, on $L_2(\mathbb{R})$, a bounded operator corresponds with a stable system.

**Definition** Let $\mathcal{H}$ and $\mathcal{N}$ be Hilbert spaces and let $K : \mathcal{H} \to \mathcal{N}$ be a linear operator. The norm of $K$, denoted $\|K\|$, is defined by

$$\|K\| = \sup \{\|Kh\|_N : h \in \mathcal{H}, \|h\|_\mathcal{H} \leq 1\}.$$  \hspace{1cm} (5.1)

If $\|K\| < \infty$, then $K$ is said to be *bounded*.

**Definition** $\mathcal{B}(\mathcal{H}, \mathcal{N})$ is the set of all linear bounded operators from $\mathcal{H}$ to $\mathcal{N}$. $\mathcal{B}(\mathcal{H})$ is the set of all linear bounded operators from $\mathcal{H}$ to $\mathcal{H}$.

There are equivalent definitions of the norm of an operator, given by the following theorem.
Theorem 5.2.1 Let $\mathcal{H}$ and $\mathcal{N}$ be Hilbert spaces, and let $K : \mathcal{H} \to \mathcal{N}$ be a linear operator. Then

$$
\|K\| = \sup \{\|K\|_\mathcal{N} : h \in \mathcal{H}, \|h\|_\mathcal{H} \leq 1\}
$$

$$
= \sup \{\|K\|_\mathcal{N} : h \in \mathcal{H}, \|h\|_\mathcal{H} = 1\}
$$

$$
= \sup \left\{ \frac{\|K\|_\mathcal{N}}{\|h\|_\mathcal{H}} : h \in \mathcal{H}, \|h\|_\mathcal{H} \neq 0 \right\}
$$

$$
= \inf \left\{ c : \|K\|_\mathcal{N} \leq c \|h\|_\mathcal{H}, \text{ for all } h \in \mathcal{H} \right\}. \quad (5.2)
$$

Proof See [84].

Definition Let $\mathcal{H}$ and $\mathcal{N}$ be Hilbert spaces and $K \in \mathcal{B}(\mathcal{H}, \mathcal{N})$. The adjoint of $K$, denoted by $K^\ast$, is the unique operator $A \in \mathcal{B}(\mathcal{N}, \mathcal{H})$ such that $\langle Kh, g \rangle_\mathcal{N} = \langle h, Ag \rangle_\mathcal{H}$ for all $h \in \mathcal{H}$ and for all $g \in \mathcal{N}$ [20].

Definition An operator $K \in \mathcal{B}(\mathcal{H})$ is said to be Hermitian if $K = K^\ast$.

Hermitian operators have special properties that will be used in the spectral theorems.

Just as we have an equivalence relation for Hilbert spaces, we would like one for operators in Hilbert spaces.

Definition Let $\mathcal{H}$ and $\mathcal{N}$ be Hilbert spaces with $A \in \mathcal{B}(\mathcal{H})$ and $B \in \mathcal{B}(\mathcal{N})$. $A$ and $B$ are unitarily equivalent if there exists an isomorphism $U : \mathcal{H} \to \mathcal{N}$ such that

$$
A = U^{-1}BU.
$$
Being unitarily equivalent is an equivalence relation for bounded operators on isomorphic Hilbert spaces [20]. If $A$ and $B$ are unitarily equivalent operators, we may consider them the same operator because corresponding elements in $\mathcal{H}$ and $\mathcal{N}$ are mapped to corresponding elements in $\mathcal{H}$ and $\mathcal{N}$ by $A$ and $B$, respectively. In isomorphic Hilbert spaces, we may construct realizations of an operator that are unitarily equivalent. The analysis performed on an operator is valid for any unitarily equivalent operator. In Section 6.1 we show four representations for a Hankel operator, which will be used to simplify the estimation of the singular values of a Hankel operator by causing calculations to be performed on the unitarily equivalent operator for which the calculations are easier.

5.3 Compact Operators

Many of the properties of linear operators on finite-dimensional spaces may be generalized to a certain class of linear operators on infinite-dimensional spaces. This class is known as the set of compact operators.

**Definition** Let $\mathcal{H}$ and $\mathcal{N}$ be Hilbert spaces and let $H_1 = \{h \in \mathcal{H} : \|h\| \leq 1\}$. A linear operator $K : \mathcal{H} \to \mathcal{N}$ is **compact** if $K(H_1)$ has a compact closure in $\mathcal{N}$. The set of compact operators from $\mathcal{H}$ to $\mathcal{N}$ is denoted $\mathcal{B}_0(\mathcal{H}, \mathcal{N})$, and $\mathcal{B}_0(\mathcal{H}) = \mathcal{B}_0(\mathcal{H}, \mathcal{H})$.

**Definition** The rank of an operator $K$ is the dimension of the range of $K$. $K$ is said to be a **finite-rank** operator if range($K$) is finite dimensional. The set of all finite-rank linear operators from $\mathcal{H}$ to $\mathcal{N}$ is denoted $\mathcal{B}_{00}(\mathcal{H}, \mathcal{N})$, and $\mathcal{B}_{00}(\mathcal{H}) = \mathcal{B}_{00}(\mathcal{H}, \mathcal{H})$.
If \( K \in \mathcal{B}(\mathcal{H}, \mathcal{N}) \), then \( K(H_1) \) is bounded; however, in an infinite-dimensional space, this does not imply that the closure of \( K(H_1) \) is compact. Thus the definition of compact operators is useful, as it specifies a class of operators that has some properties similar to those of operators on finite-dimensional spaces. Specifically, a useful interpretation is that a compact operator has countable rank.

**Theorem 5.3.1** Let \( \mathcal{H} \) and \( \mathcal{N} \) be Hilbert spaces. Then

1. \( \mathcal{B}_0(\mathcal{H}, \mathcal{N}) \subset \mathcal{B}(\mathcal{H}, \mathcal{N}) \subset \mathcal{B}_0(\mathcal{H}, \mathcal{N}) \)

2. Let \( K \in \mathcal{B}(\mathcal{H}, \mathcal{N}) \). Then the following are equivalent:
   
   (a) \( K \) is compact.
   
   (b) \( K^* \) is compact.
   
   (c) There exists \( \{K_n\} \subset \mathcal{B}_0(\mathcal{H}, \mathcal{N}) \) such that \( \|K - K_n\| \to 0 \).
   
   (d) There exists \( \{K_n\} \subset \mathcal{B}_0(\mathcal{H}, \mathcal{N}) \) such that \( \|K - K_n\| \to 0 \).

**Proof** See [20] and [10].

This theorem indicates that an operator is compact if and only if it can be approximated with any degree of accuracy by a finite-rank operator.

The next result shows that the composition of a compact operator with a bounded operator is compact. Since compact operators are bounded, the composition of two compact operators is itself compact. This theorem is given in [20] for Banach spaces, however, since any Hilbert space is a Banach space, it holds for Hilbert spaces.

**Theorem 5.3.2** Let \( \mathcal{H}, \mathcal{N} \) and \( \mathcal{M} \) be Hilbert spaces. Then
1. If $K \in \mathcal{B}_0 (\mathcal{H}, \mathcal{N})$ and $A \in \mathcal{B} (\mathcal{N}, \mathcal{M})$, then $AK \in \mathcal{B}_0 (\mathcal{H}, \mathcal{M})$.

2. If $K \in \mathcal{B}_0 (\mathcal{H}, \mathcal{N})$ and $A \in \mathcal{B} (\mathcal{M}, \mathcal{H})$, then $KA \in \mathcal{B}_0 (\mathcal{M}, \mathcal{N})$.

**Proof** See [20].

### 5.4 The Spectral Theorem for Compact Hermitian Operators

The spectral theorem for compact Hermitian operators gives a decomposition of a compact Hermitian operator that is an extension of the diagonalization of a matrix using the eigenvectors of the matrix as a basis. Here we see that the rank of a compact operator is countable. This is a step from uncountably-infinite-rank operators toward finite-rank operators.

**Theorem 5.4.1** Let $\mathcal{H}$ be a Hilbert space. $K$ is a compact Hermitian operator on $\mathcal{H}$ if and only if there exists a sequence $\{\lambda_k\}$ of real numbers that tends toward zero and an orthonormal basis $\{v_k\}$ of $\mathcal{H}$ such that for any $h \in \mathcal{H}$

$$Kh = \sum_{k=1}^{\infty} \lambda_k \langle h, v_k \rangle v_k.$$  

**Proof** See [20].

This is called the spectral decomposition of $K$. The elements of the sequence $\{\lambda_k\}$ are called the eigenvalues of the operator, and the basis $\{v_k\}$ are the eigenvectors of the operator. Note that $Kv_k = \lambda_k v_k$. 

110
Note that if $K$ is a compact operator, then by Theorem 5.3.1, $K^*$ is also a compact operator, and subsequently, by Theorem 5.3.2, $K^*K$ is a compact operator. Since $K^{**} = K$, for all $u, v \in \mathcal{H}$, $\langle K^*Ku, v \rangle = \langle Ku, Kv \rangle = \langle u, K^*Kv \rangle$, so $K^*K$ is also Hermitian. We now look at the Schmidt expansion of a compact operator.

**Theorem 5.4.2** Let $\mathcal{H}$ be a Hilbert space. $K$ acting on $\mathcal{H}$ is compact if and only if there exist orthonormal sequences $\{u_k\}$ and $\{w_k\}$ and scalars $\{\sigma_k\}$ decreasing to 0 such that

$$Kh = \sum_{k=1}^{\infty} \sigma_k \langle h, u_k \rangle w_k.$$ 

**Proof** See [73].

This is called the Schmidt decomposition of $K$. The elements of $\{\sigma_k\}$ are the singular values of the operator, and the pairs $\{(u_k, w_k)\}$ are the Schmidt pairs of the operator. $\{\sigma_k^2\}$ are the eigenvalues of $K^*K$, and $\{u_k\}$ and $\{w_k\}$ are the eigenvectors of $K^*K$ and $KK^*$ respectively [21]. Further, $Ku_k = \sigma_kw_k$ and $K^*w_k = \sigma_ku_k$ [21].

An equivalent definition for the singular values is given by [75] in the next theorem.

**Theorem 5.4.3** Let $\mathcal{H}$ be a Hilbert space and $K \in B_0(\mathcal{H}, \mathcal{N})$. Then the $n^{th}$ singular value of $K$, denoted $\sigma_n(K)$ is given by

$$\sigma_n(K) = \inf \{\|K - T\| : T \in B_{00}(\mathcal{H}, \mathcal{N}), \operatorname{rank}(T) < n\}.$$ 

**Proof** See [75].
For a compact Hermitian operator $K$, the singular values of $K$ are related to the eigenvalues of $K$, and the Schmidt pairs of $K$ are related to the eigenvectors of $K$.

**Theorem 5.4.4** Let $K : \mathcal{H} \to \mathcal{H}$ be a compact Hermitian operator on a Hilbert space $\mathcal{H}$ with eigenvalues $\{\lambda_k\}$, eigenvectors $\{v_k\}$, singular values $\{\sigma_k\}$, and Schmidt pairs $\{(u_k, w_k)\}$. Then, $\sigma_k = |\lambda_k|$, $u_k = v_k$, and $w_k = \text{sgn}(\lambda_k) v_k$ for $k \in \mathbb{N}$.

**Proof** Because $K$ is a compact Hermitian operator, by Theorem 5.4.1, $K$ has eigenvalues $\{\lambda_k\}$ and eigenvectors $\{v_k\}$. For each $k \in \mathbb{N}$, set $u_k = v_k$, $\sigma_k = |\lambda_k|$, and $w_k = \text{sgn}(\lambda_k) v_k$. By Theorem 5.4.2, for any $\ell \in \mathcal{H}$

$$
\sum_{k=1}^{\infty} \sigma_k \langle h, u_k \rangle w_k = \sum_{k=1}^{\infty} |\lambda_k| \langle h, v_k \rangle \text{sgn}(\lambda_k) v_k
$$

$$
= \sum_{k=1}^{\infty} \text{sgn}(\lambda_k) |\lambda_k| \langle h, v_k \rangle v_k = \sum_{k=1}^{\infty} \lambda_k \langle h, v_k \rangle v_k = Kh.
$$

Thus we have shown that $\{|\lambda_k|\} \subset \{\sigma_k\}$ and that $\{v_k\} \subset \{u_k\}$.

Consider $h \in \mathcal{H}$ such that $h \not\in \{v_k\}$ and $h \neq 0$. Then, since $\{v_k\}$ is a basis for $\mathcal{H}$, $h$ can be written as the linear combination of elements in $\{v_k\}$, and $h$ is not orthogonal to at least one $v_k$. Hence, $h$ is not orthogonal to at least one $u_k$. Since $\{u_k\}$ is also a basis for $\mathcal{H}$, $h \not\in \{u_k\}$. Subsequently, $(h, Kh)$ is not a Schmidt pair for $K$. We have shown that the only singular values of $K$ are related to the eigenvalues of $K$, and the only Schmidt pairs of $K$ are related to the eigenvalues of $K$. The result follows. \[\blacksquare\]
The Schmidt decomposition fully characterizes a compact operator on a Hilbert space. The Schmidt decomposition is used in the model reduction and $H_\infty$-control problems [73].

The ultimate goal of this research is to obtain estimates on the singular values of the Hankel operator for fractional-order systems. A process by which these singular values may be estimated is given in Section 7.1.

5.5 Operators on $L_2(\mathbb{R})$

We now move from discussion of operators on a general Hilbert space, and restrict ourselves to operators on a specific Hilbert space, $L_2(\mathbb{R})$. Before a discussion of operators on $L_2(\mathbb{R})$ can begin, we introduce several spaces related to $L_2(\mathbb{R})$. We will be especially interested in the conditions under which Hankel operators on these spaces are unitarily equivalent. Then we will be able to consider the same operator in the space in which the properties and calculation in the space are most convenient.

5.5.1 Related Spaces

**Definition** We define the spaces $L_2(\mathbb{R})$, $L_2(\mathbb{R}^+)$, $L_2(\mathbb{R}^-)$, and $L_2(i\mathbb{R})$ by

$$L_2(\mathbb{R}) = \left\{ f : \int_{-\infty}^{\infty} |f(t)|^2 \, dt < \infty \right\},$$

$$L_2(\mathbb{R}^+) = \{ f \in L_2(\mathbb{R}) : f(t) = 0 \text{ for } t < 0 \},$$
\[ L_2(\mathbb{R}_-) = \{ f \in L_2(\mathbb{R}) : f(t) = 0 \text{ for } t \geq 0 \}, \]

and

\[ L_2(j\mathbb{R}) = \left\{ F : \int_{-\infty}^{\infty} |F(i\omega)|^2 d\omega < \infty \right\}, \]

where \( F \) is defined on \( j\mathbb{R} \), along with the norms

\[ \|f\|_2 = \left( \int_{-\infty}^{\infty} |f(t)|^2 dt \right)^{\frac{1}{2}} \]

for \( f \in L_2(\mathbb{R}) \), \( f \in L_2(\mathbb{R}_+) \), or \( f \in L_2(\mathbb{R}_-) \) and

\[ \|F\|_2 = \left( \frac{1}{2\pi} \int_{-\infty}^{\infty} |F(i\omega)|^2 d\omega \right)^{\frac{1}{2}} \]

for \( F \in L_2(j\mathbb{R}) \), \( L_2(\mathbb{R}), L_2(\mathbb{R}_+), \) and \( L_2(\mathbb{R}_-) \), have been shown to be Hilbert spaces with the usual inner products in Theorem 5.1.1. It can be easily verified that \( L_2(j\mathbb{R}) \) is Hilbert space with inner product

\[ \langle F_1, F_2 \rangle = \frac{1}{2\pi} \int_{-\infty}^{\infty} F_1(i\omega)\overline{F_2(i\omega)} d\omega, \]

the usual definition of an inner product multiplied by a constant.

For the discussion on operators on \( L_2(\mathbb{R}) \), the spaces \( L_1(\mathbb{R}) \) and \( L_\infty(j\mathbb{R}) \) will prove useful. Thus, we define those spaces here.
**Definition** Define the space $L_1(\mathbb{R})$ by

$$L_1(\mathbb{R}) = \left\{ f : \int_{-\infty}^{\infty} |f(t)| \, dt < \infty \right\},$$

along with the norm

$$\|f\|_1 = \int_{-\infty}^{\infty} |f(t)| \, dt.$$ 

for $f \in L_1(\mathbb{R})$. Define the space $L_\infty(i\mathbb{R})$ by

$$L_\infty(i\mathbb{R}) = \{ G : |G(i\omega)| \text{ is essentially bounded on } i\mathbb{R} \}$$

along with the norm

$$\|G\|_\infty = \text{ess sup} \{ |G(i\omega)| : \omega \in \mathbb{R} \}$$

for $G \in L_\infty(i\mathbb{R})$.

We wish to show that $L_2(\mathbb{R}) \cong L_2(i\mathbb{R})$. To do that we require some definitions.

**Definition** A function $f : \mathbb{R} \to \mathbb{R}$ is called *rapidly decreasing* if $f$ is infinitely differentiable and for all $m, n \in \mathbb{N}$

$$\|f\|_{m,n} = \sup \{ |t^m f^{(n)}(t)| : t \in \mathbb{R} \} < \infty. \quad (5.3)$$

The *Schwartz space*, $\mathcal{S}$ or $\mathcal{S}(\mathbb{R})$, is the set of all rapidly decreasing functions on $\mathbb{R}$. 

115
Recall that a set $A$ is dense in the set $B$ if $A \subset B$ and $B = \overline{A}$. Intuitively, this means that any member of $B$ can be approximated arbitrarily closely by a member of $A$.

**Theorem 5.5.1** If $1 \leq p \leq \infty$, $S \subset L_p(\mathbb{R})$. If $1 \leq p < \infty$, then $S$ is dense in $L_p(\mathbb{R})$.

**Proof** See [20].

This means that any element of $L_p(\mathbb{R})$ can be approximated arbitrarily closely by an element of $S$.

The Fourier transform is a well-known tool that will help in showing that $L_2(\mathbb{R}) \cong L_2(i\mathbb{R})$.

**Definition** Let $f \in L_1(\mathbb{R})$. Then the Fourier transform of $f$, denoted $F$, is defined by

$$F(i\omega) = \int_{-\infty}^{\infty} e^{-i\omega t} f(t) dt.$$  

Note that $F(i\omega)$ exists and is finite for all $\omega \in \mathbb{R}$.

Because the Fourier transform is only defined for $f \in L_1(\mathbb{R})$, it is not the isomorphism that we are seeking. However, $S \subset L_1(\mathbb{R})$, so the Fourier transform is defined on $S$, and $S$ is dense in $L_2(\mathbb{R})$. This leads to the isomorphism between $L_2(\mathbb{R})$ and $L_2(i\mathbb{R})$ that we are seeking.

**Theorem 5.5.2 (Plancherel’s Theorem)** If $f \in S$, then $\|F\|_2 = \|f\|_2$ and the Fourier transform extends to a surjective isomorphism from $L_2(\mathbb{R})$ to $L_2(i\mathbb{R})$.

**Proof** See [20].
This surjective isomorphism is sometimes called the Plancherel transform, and is denoted $\mathcal{F}$. Although, strictly speaking, the Plancherel transform is an extension of the Fourier transform, $\mathcal{F}$ is simply called the Fourier transform. Since $\mathcal{F}$ is an isomorphism, $L_2(\mathbb{R}) \cong L_2(i\mathbb{R})$. Further, the norms of two elements in $L_2(\mathbb{R})$ and $L_2(i\mathbb{R})$ related by $\mathcal{F}$ are equal.

We now establish the relationship between the space $L_2(\mathbb{R})$ and the spaces $L_2(\mathbb{R}^+)$ and $L_2(\mathbb{R}^-)$.

**Theorem 5.5.3** $L_2(\mathbb{R}) = L_2(\mathbb{R}^+) \oplus L_2(\mathbb{R}^-)$

**Proof** Recall that $L_2(\mathbb{R}^+) \subset L_2(\mathbb{R})$ and $L_2(\mathbb{R}^-) \subset L_2(\mathbb{R})$. Note that $L_2(\mathbb{R}^+) \cap L_2(\mathbb{R}^-) = \{0\}$. Let $f_+ \in L_2(\mathbb{R}^+)$ and $f_- \in L_2(\mathbb{R}^-)$. Then $f = f_+ + f_- \in L_2(\mathbb{R})$, so $L_2(\mathbb{R}^+) \oplus L_2(\mathbb{R}^-) \subset L_2(\mathbb{R})$. Let $g \in L_2(\mathbb{R})$. Define

$$g_+(t) = \begin{cases} 0, & t < 0 \\ g(t), & t \geq 0 \end{cases}$$

and

$$g_-(t) = \begin{cases} g(t), & t < 0 \\ 0, & t \geq 0 \end{cases}.$$  

It is clear that $g_- \in L_2(\mathbb{R}^-)$ and $g_+ \in L_2(\mathbb{R}^+)$ and that $g = g_- + g_+$. Hence, $L_2(\mathbb{R}) \subset L_2(\mathbb{R}^+) \oplus L_2(\mathbb{R}^-)$. Hence, $L_2(\mathbb{R}) = L_2(\mathbb{R}^+) \oplus L_2(\mathbb{R}^-)$. 

**Lemma 5.5.4** Any function $f$ that has a Fourier transform $F(i\omega)$ has a Laplace transform $F(s)$. Further the two are related by $F(i\omega) = F(s)|_{s=i\omega}$.
Proof Let $f$ have a Fourier transform $F(i\omega) = \int_{-\infty}^{\infty} f(t)e^{-i\omega t}dt$. Then the Laplace transform integral $\int_{-\infty}^{\infty} f(t)e^{-st}dt$ converges for $s = i\omega$ for all $\omega \in \mathbb{R}$, and is exactly the same as the Fourier transform of $f$.

For a function $f$ with a Fourier transform $F(i\omega)$, $F(s)$ exists and by Theorem 2.2.1 is analytic on $i\mathbb{R}$ since $i\mathbb{R} \subset \mathcal{R}$. Hence $F(s)$ can be obtained via analytic continuation to a unique function [45].

Using the analytic continuation of elements of $L_2(i\mathbb{R})$, we now define Hardy spaces $H_2(\mathbb{C}^+), H_2(\mathbb{C}^-)$, and $H_\infty(\mathbb{C}^+)$.  

**Definition** Define $H_2(\mathbb{C}^+), H_2(\mathbb{C}^-)$, and $H_\infty(\mathbb{C}^+)$ by

$$H_2(\mathbb{C}^+) = \left\{ F \in L_2(i\mathbb{R}) : F(s) \text{ is analytic in } \mathbb{C}^+ \right\},$$

$$H_2(\mathbb{C}^-) = \left\{ F \in L_2(i\mathbb{R}) : F(s) \text{ is analytic in } \mathbb{C}^- \right\},$$

and

$$H_\infty(\mathbb{C}^+) = \left\{ G \in L_\infty(i\mathbb{R}) : G(s) \text{ is analytic in } \mathbb{C}^+ \right\}.$$  

Note that $H_2(\mathbb{C}^+)$ and $H_2(\mathbb{C}^-)$ inherit the inner product and induced norm of $L_2(i\mathbb{R})$, and note that $H_\infty(\mathbb{C}^+)$ inherits the norm of $L_\infty(i\mathbb{R})$. $H_2(\mathbb{C}^+)$ and $H_2(\mathbb{C}^-)$ are Hilbert spaces [73].

Finally, another space that will prove useful in the discussion of operators on $L_2(\mathbb{R})$ is $RH_\infty(\mathbb{C}^+)$.
**Definition** Define the space, $RH_{\infty} (\mathbb{C}^\dagger)$ by

$$RH_{\infty} (\mathbb{C}^\dagger) = H_{\infty} (\mathbb{C}^\dagger) \cap \mathbb{R}(s).$$

Since $L_2 (\mathbb{R}) \cong L_2 (i\mathbb{R})$ and $L_2 (\mathbb{R}) = L_2 (\mathbb{R}^+) \oplus L_2 (\mathbb{R}^-$), we would like a similar decomposition of $L_2 (i\mathbb{R})$. The next result shows the correspondence between $L_2 (\mathbb{R}^+)$ and $H_2 (\mathbb{C}^\dagger)$ and between $L_2 (\mathbb{R}^-)$ and $H_2 (\mathbb{C}^\dagger)$, which does imply that $L_2 (i\mathbb{R}) = H_2 (\mathbb{C}^\dagger) \oplus H_2 (\mathbb{C}^\dagger)$.

**Theorem 5.5.5** The Laplace transform is an isomorphism from $L_2 (\mathbb{R}^+)$ to $H_2 (\mathbb{C}^\dagger)$ and from $L_2 (\mathbb{R}^-)$ to $H_2 (\mathbb{C}^\dagger)$

**Proof** See [74].

**Corollary 5.5.6** $L_2 (\mathbb{R}^+) \cong H_2 (\mathbb{C}^\dagger)$ and $L_2 (\mathbb{R}^-) \cong H_2 (\mathbb{C}^\dagger)$.

**Corollary 5.5.7** $L_2 (i\mathbb{R}) = H_2 (\mathbb{C}^\dagger) \oplus H_2 (\mathbb{C}^\dagger)$

We define another $L_2$-space and related spaces on the unit circle $\mathbb{T}$.

**Definition** Define the norms $\|f\|_2$ and $\|f\|_\infty$ by

$$\|f\|_2 = \left( \frac{1}{2\pi} \int_0^{2\pi} |f(e^{i\theta})|^2 \, d\theta \right)^{\frac{1}{2}}$$

and

$$\|f\|_\infty = \text{ess sup} \{ |f(e^{i\theta})| : \theta \in [0, 2\pi] \}.$$
Define the spaces $L_2(\mathbb{T})$ and $L_\infty(\mathbb{T})$ by

$$L_2(\mathbb{T}) = \{ f : \|f\|_2 < \infty \}$$

and

$$L_\infty(\mathbb{T}) = \{ f : \|f\|_\infty < \infty \}.$$

The inner product for $L_2(\mathbb{T})$ is defined by

$$\langle f, g \rangle = \frac{1}{2\pi} \int_0^{2\pi} f(e^{i\theta}) \overline{g(e^{i\theta})} d\theta.$$

**Theorem 5.5.8** The set of functions $\{e^{in\theta} : n \in \mathbb{Z}\}$ is a basis for $L_2(\mathbb{T})$.

**Proof** See [73].

Thus, if $f \in L_2(\mathbb{T})$, it can be written as a Laurent series in $e^{i\theta}$. Therefore, we can consider $f(z)$ as an analytic function on $\mathbb{T}$, which extends uniquely via analytic continuation to a function on $\mathbb{C}$. We can write $f(z)$ as

$$f(z) = \sum_{k=-\infty}^{\infty} \hat{\phi}(k) z^k,$$

where

$$\hat{\phi}(k) = \langle f, z^k \rangle.$$

We can also define Hardy spaces on the unit disc $\mathbb{D}$. 
Definition Define the norms $\|f\|_{H_2}$ and $\|f\|_{H_{\infty}}$ by

$$\|f\|_{H_2} = \left( \frac{1}{2\pi} \int_0^{2\pi} |f(e^{i\theta})|^2 \, d\theta \right)^{\frac{1}{2}}$$

and

$$\|f\|_{H_{\infty}} = \text{ess sup} \{|f(z)| : z \in \mathbb{D}\}.$$ 

Define $H_2(\mathbb{D})$ as the space of analytic functions on $\mathbb{D}$ such that $\|f\|_{H_2} < \infty$. Similarly, we define $H_{\infty}(\mathbb{D})$ as the space of analytic functions on $\mathbb{D}$ such that $\|f\|_{H_{\infty}} < \infty$.

Definition Let $S \subset \mathbb{Z}$. Define the space $\ell_2(S)$ by

$$\ell_2(S) = \left\{ \{x_k\} : \sum_S |x_k|^2 < \infty \right\}.$$ 

$\ell_2(S)$ along with the inner product

$$\langle \{a_k\}, \{b_k\} \rangle = \sum_S a_k \overline{b_k}$$

is a Hilbert space.

We note an alternate definition of $H_2(\mathbb{D})$.

Theorem 5.5.9 $H_2(\mathbb{D})$ can be written as

$$H_2(\mathbb{D}) = \left\{ f \in L_2(\mathbb{T}) : \hat{\phi}(k) = 0 \text{ for all } k < 0 \right\}.$$
Proof By Theorem 5.5.10 $H_2(\mathbb{D}) \subset L_2(\mathbb{T})$. Let $f(z) \in L_2(\mathbb{T})$. Suppose $\hat{\phi}(k) \neq 0$ for some $k < 0$. Then $f(z)$ is not analytic on $\mathbb{D}$ so $f(z) \notin H_2(\mathbb{D})$. Thus, $H_2(\mathbb{D}) \subset \left\{ f \in L_2(\mathbb{T}) : \hat{\phi}(k) = 0 \text{ for all } k < 0 \right\}$. Suppose that $\hat{\phi}(k) = 0$ for all $k < 0$. Then $f(z)$ is analytic in $\mathbb{D}$. Thus, $\left\{ f \in L_2(\mathbb{T}) : \hat{\phi}(k) = 0 \text{ for all } k < 0 \right\} \subset H_2(\mathbb{D})$ and $H_2(\mathbb{D}) = \left\{ f \in L_2(\mathbb{T}) : \hat{\phi}(k) = 0 \text{ for all } k < 0 \right\}$.

We now describe the relationships between these spaces and previously defined spaces.

Theorem 5.5.10 The following relationships hold:

1. $L_2(\mathbb{R}) = L_2(\mathbb{R}_-) \oplus L_2(\mathbb{R}_+)$

2. $L_2(i\mathbb{R}) = H_2(\mathbb{C}^-) \oplus H_2(\mathbb{C}^+)$

3. $L_2(\mathbb{T}) = H_2(\mathbb{D})^\perp \oplus H_2(\mathbb{D})$

4. $\ell_2(\mathbb{Z}) = \ell_2(\mathbb{Z}_-) \oplus \ell_2(\mathbb{N})$

5. $L_2(\mathbb{R}) \cong L_2(i\mathbb{R}) \cong L_2(\mathbb{T}) \cong \ell_2(\mathbb{Z})$

6. $L_2(\mathbb{R}_+) \cong H_2(\mathbb{C}^+) \cong H_2(\mathbb{D}) \cong \ell_2(\mathbb{N})$

7. $L_2(\mathbb{R}_-) \cong H_2(\mathbb{C}^-) \cong H_2(\mathbb{D})^\perp \cong \ell_2(\mathbb{Z}_-)$

8. $H_\infty(\mathbb{D}) \cong H_\infty(\mathbb{C}^+)$

Proof See [73] and [75].

We now define two orthogonal projection operators, one from $L_2(i\mathbb{R})$ to $H_2(\mathbb{C}^+)$ and the second from $L_2(\mathbb{T})$ to $H_2(\mathbb{D})$. 

122
**Definition** Let $F(s) \in L_2(i\mathbb{R})$. There exist unique functions $F_-(s) \in H_2(\mathbb{C}^-)$ and $F_+(s) \in H_2(\mathbb{C}^+)$ such that $F(s) = F_-(s) + F_+(s)$. Then $\Pi_+$ the orthogonal projection operator onto $H_2(\mathbb{C}^+)$ is given by $\Pi_+ F(s) = F_+(s)$, and $\Pi_-$ the orthogonal projection operator onto $H_2(\mathbb{C}^-)$ is given by $\Pi_- F(s) = F_-(s)$.

**Definition** Let $f(z) \in L_2(\mathbb{T})$. There exist unique functions $f_-(z) \in H_2(\mathbb{D})^\perp$ and $f_+(z) \in H_2(\mathbb{D})$ such that $f(z) = f_-(z) + f_+(z)$. Then $\Pi_+$ the orthogonal projection operator onto $H_2(\mathbb{D})$ is given by $\Pi_+ f(z) = f_+(z)$, and $\Pi_-$ the orthogonal projection operator onto $H_2(\mathbb{D})^\perp$ is given by $\Pi_- f(z) = f_-(z)$.

It will be clear from the context whether $\Pi_+$ is the orthogonal projection onto $H_2(\mathbb{C}^+)$ or $H_2(\mathbb{D})$ and whether $\Pi_-$ is the orthogonal projection operator onto $H_2(\mathbb{C}^-)$ or $H_2(\mathbb{D})^\perp$.

Note that $H_2(\mathbb{D})$ inherits the inner product of $L_2(\mathbb{T})$ and that $H_2(\mathbb{D})$ is a Hilbert space [73].

5.5.2 Convolution Operators on $L_2(\mathbb{R})$

Having built a general abstract framework in which to consider convolution operators, we now discuss such operators on $L_2(\mathbb{R})$.

Let $\mathcal{G} \in \mathcal{B}(L_2(\mathbb{R}))$ be the convolution operator with impulse response $\tilde{g}(t)$, that is

$$(\mathcal{G} u)(t) = \int_{-\infty}^{\infty} \tilde{g}(t - \tau) u(\tau) d\tau.$$
Let $G(s) = \mathcal{L}\{\tilde{g}(t)\}$ be the transfer function for the system whose convolution operator is $\mathcal{G}$.

**Theorem 5.5.11**

1. If $\tilde{g} \in L_1(\mathbb{R})$, then $G \in L_\infty(i\mathbb{R})$ with \( \|G\|_{\infty} \leq \|g\|_1 \).

2. If $\tilde{g} \in L_1(\mathbb{R})$ and $\tilde{g}(t) = 0$ for $t < 0$, then $G \in H_\infty(\mathbb{C}^+)$. 

**Proof**

1. Let $\tilde{g} \in L_1(\mathbb{R})$. For any $\omega \in \mathbb{R}$,

\[
|G(i\omega)| = \left| \int_{-\infty}^{\infty} \tilde{g}(t)e^{-i\omega t} dt \right| \leq \int_{-\infty}^{\infty} |\tilde{g}(t)e^{-i\omega t}| dt = \int_{-\infty}^{\infty} |\tilde{g}(t)| e^{-i\omega t} dt = \int_{-\infty}^{\infty} |\tilde{g}(t)| dt
\]

Since $|G(i\omega)| \leq \|\tilde{g}\|_1$ for any $\omega \in \mathbb{R}$, $|G(i\omega)|$ has a uniform bound on $i\mathbb{R}$, and it follows that

\[
\|G\|_{\infty} = \text{ess sup} \{ |G(i\omega)| : \omega \in \mathbb{R} \} \leq \|\tilde{g}\|_1 < \infty.
\]

Thus, $G \in L_\infty(i\mathbb{R})$, and $\|G\|_{\infty} \leq \|\tilde{g}\|_1$.

2. Let $\tilde{g} \in L_1(\mathbb{R})$ and $g(t) = 0$ for $t < 0$. Since $\tilde{g} \in L_1(\mathbb{R})$, by the first part of the theorem, $G \in L_\infty(i\mathbb{R})$. Suppose that $s \in \mathbb{C}^+$. Hence $|e^{-st}| \leq 1$ for $t > 0$. 

124
Then, since \( \tilde{g}(t) = 0 \) for \( t < 0 \), \( G(s) \) is given by

\[
|G(s)| = \left| \int_{-\infty}^{\infty} \tilde{g}(t) e^{-st} \, dt \right| = \left| \int_{0}^{\infty} \tilde{g}(t) e^{-st} \, dt \right| \leq \int_{0}^{\infty} |\tilde{g}(t)| e^{-st} \, dt
\]

\[
\leq \int_{0}^{\infty} |\tilde{g}(t)| \cdot 1 \, dt = \int_{-\infty}^{\infty} |\tilde{g}(t)| \, dt = \|\tilde{g}\|_1 < \infty.
\]

Thus, the integral converges for \( s \in \mathbb{C}^+ \), so \( \mathbb{C}^+ \subset \mathcal{R} \), and hence by Theorem 2.2.1 \( G(s) \) is analytic on \( \mathbb{C}^+ \). Subsequently, \( G \in H_\infty(\mathbb{C}^+) \).

**Theorem 5.5.12** If \( G \in L_\infty(i\mathbb{R}) \), then \( \mathcal{G} \) is a bounded operator in \( L_2(\mathbb{R}) \) with \( \|\mathcal{G}\| = \|G\|_\infty \).

**Proof** Let \( u \in L_2(\mathbb{R}) \) and let \( U = \mathcal{F} u \in L_2(i\mathbb{R}) \). Then

\[
\|\mathcal{G} u\|_2^2 = \|\mathcal{F}(\mathcal{G} u)\|_2^2 = \|G U\|_2^2 = \frac{1}{2\pi} \int_{-\infty}^{\infty} |G(i\omega) U(\omega)|^2 \, d\omega
\]

\[
= \frac{1}{2\pi} \int_{-\infty}^{\infty} |G(i\omega)|^2 |U(\omega)|^2 \, d\omega
\]

\[
\leq \|G\|_\infty^2 \frac{1}{2\pi} \int_{-\infty}^{\infty} |U(\omega)|^2 \, d\omega
\]

\[
= \|G\|_\infty^2 \|U\|_2^2 = \|G\|_\infty^2 \|u\|_2^2,
\]

Thus, \( \mathcal{G} \in \mathcal{B}(L_2(\mathbb{R})) \) with \( \|\mathcal{G}\| \leq \|G\|_\infty \).

Assume that \( G(i\omega) \neq 0 \). Let \( \epsilon > 0 \) be given. Define \( E \) by

\[
E = \{ \omega \in \mathbb{R} : |G(i\omega)| > \|G\|_\infty - \epsilon \}.
\]
Clearly, $E$ has positive measure, else

$$\|G(i\omega)\|_{\infty} = \operatorname{ess sup}\{ |G(i\omega)| : \omega \in \mathbb{R} \} \leq \|G(i\omega)\|_{\infty} - \epsilon.$$ 

If $E$ has infinite measure, then we wish to replace it with a set that has finite measure. We can choose $I_{\Omega} = [-\Omega, \Omega]$, such that $\hat{E} = E \cap I_{\Omega}$ and $\hat{E}$ has finite, positive measure.

We complete the proof replacing $E$ by $\hat{E}$ if $|E| = \infty$. So, without loss of generality, we assume that $|E| < \infty$.

Define $U(i\omega) \in L_{2}(i\mathbb{R})$ by

$$U(i\omega) = \begin{cases} 
1, & \omega \in E \\
0, & \omega \notin E
\end{cases}.$$ 

Note that $\|U\|^{2}_{2} = \frac{1}{2\pi} |E| < \infty$, where $|E|$ is the measure of $E$.

Let $u = F^{-1}\{U\}$. By Plancherel’s theorem, $\|u\|_{2} = \|U\|_{2}$. Then $\|(Gu)(t)\|^{2}_{2}$ is given by

$$\|Gu\|_{2}^{2} = \|GU\|_{2}^{2} = \frac{1}{2\pi} \int_{-\infty}^{\infty} |G(i\omega)U(i\omega)|^{2} d\omega$$

$$\geq \frac{1}{2\pi} \int_{E} |G(i\omega)U(i\omega)|^{2} \geq (\|G(i\omega)\|_{\infty} - \epsilon)^{2} \frac{1}{2\pi} |E|$$

$$= (\|G\|_{\infty} - \epsilon)^{2} \|U\|_{2}^{2} = (\|G\|_{\infty} - \epsilon)^{2} \|u\|_{2}^{2}.$$
Hence,

\[ \frac{\|Gu\|_2}{\|u\|_2} \geq \|G\|_\infty - \epsilon. \]

Since \( \epsilon \) is arbitrary, \( \|G\| \geq \|G\|_\infty \). Subsequently, \( \|G\| = \|G\|_\infty \).

Depending on the region of convergence, \( \mathcal{R} \), a first-order transfer function \( G(s) \) with its pole at \( s_+ \in \mathbb{C}_+ \) can be interpreted in two ways. Note that, by Theorem 2.2.1, \( G(s) \) cannot contain any poles in \( \mathcal{R} \) and that \( G(s) \) is analytic in \( \mathcal{R} \).

The first interpretation is that \( \mathcal{R} \) is to the right of the vertical line containing \( s_+ \). Since \( s_+ \in \mathbb{C}_+ \), \( i\mathbb{R} \not\subset \mathcal{R} \). Hence, \( \mathcal{G} \not\in \mathcal{B}(L_2(\mathbb{R})) \). The second interpretation is that \( \mathcal{R} \) is to the left of the vertical line containing \( s_+ \). Since \( s_+ \in \mathbb{C}_+ \), \( i\mathbb{R} \subset \mathcal{R} \). Hence, \( \mathcal{G} \in \mathcal{B}(L_2(\mathbb{R})) \). Further, since \( G(s) \) is analytic in \( \mathbb{C}^- \), \( G(s) \in H_2(\mathbb{C}^-) \), which means that \( g(t) \in L_2(\mathbb{R}^-) \). Thus, \( \mathcal{G} \) is anticausal. Because we wish to consider only operators in \( \mathcal{B}(L_2(\mathbb{R})) \), we use this second interpretation.

5.6 Integral Operators on \( L_2(\mathbb{R}) \)

We now consider a slightly broader class of operators on a function space, which we will take to be \( L_2(\mathbb{R}) \). In Chapter 6, it will be shown that Hankel operators are integral operators, so these results will apply to both convolution and Hankel operators.
**Definition** Let \( E \) be measurable. An *integral operator* on a function space is an operator of the form \((Ku)(t) = \int_E \tilde{g}(t, \tau) u(\tau) d\tau\). \( \tilde{g}(t, \tau) \) is called the *kernel* of the integral operator.

**Definition** An *integral equation* is an equation in which an unknown function appears inside an integral sign. An alternate definition is that an *integral equation* is an equation involving an integral operator acting on an unknown function.

### 5.6.1 General Discussion

As noted \( L_2(\mathbb{R}) \) is a Hilbert space. Consider the integral operator \( K \) on \( L_2(\mathbb{R}) \) given by

\[
(Ku)(t) = \int_0^\infty g(t, \tau) u(\tau) d\tau.
\]  

(5.4)

Information about the kernel of the operator yields information about the properties of the operator. The following theorem from [76] gives a sufficient condition on the kernel for an integral operator to be bounded.

**Theorem 5.6.1** Consider \( g(t, \tau) : E \times E \to \mathbb{F} \), and suppose that there exist constants \( c_1 \) and \( c_2 \) such that

\[
\int_E |g(t, \tau)| \, d\tau < c_1
\]

and

\[
\int_E |g(t, \tau)| \, dt < c_2.
\]

Then the integral operator \( K : L_2(E) \to L_2(E) \) with kernel \( g(t, \tau) \) is a bounded linear operator with \( \|K\| \leq \sqrt{c_1 c_2} \).
We are interested in integral operators on $L^2(E)$. We particularly want to work with bounded linear operators on $L^2(E)$, which are operators from $L^2(E)$ to $L^2(E)$. The relationship between the kernels of an integral operator and its adjoint operator is given in the next theorem.

**Theorem 5.6.2** Consider the operator $K : L^2(E) \rightarrow L^2(E)$ with kernel $g(t, \tau)$. Then the adjoint of $K$, $K^*$, is the integral operator with kernel $\overline{g(\tau, t)}$.

**Proof** See [20].

By this theorem, if $g(t, \tau) = \overline{g(\tau, t)}$, then the integral operator is Hermitian. A sufficient, but not necessary, condition on the kernel for the integral operator to be compact is given by [39].

**Theorem 5.6.3** Consider the operator $K : L^2(E) \rightarrow L^2(E)$ with kernel $g(t, \tau)$. If $g(t, \tau) \in L^2(E \times E)$, then $K$ is a compact operator with $\|K\| \leq \|g\|_2$. Such a kernel is called an $L^2$-kernel.

**Proof** See [39].

Where possible, these results will be used to demonstrate that a particular integral operator is bounded, Hermitian, or compact.
5.6.2 Degenerate Kernels

**Definition** The kernel of an integral operator is called *degenerate* or *separable* if there exist two finite sets of functions, \( \{ \alpha_k(t) \}_{k=1}^N \) and \( \{ \beta_k(\tau) \}_{k=1}^N \) such that
\[
g(t, \tau) = \sum_{k=1}^N \alpha_k(t) \beta_k(\tau).
\]

**Definition** The kernel of an integral operator is called *semi-degenerate* or *semi-separable* if there exist four finite sets of function, \( \{ \alpha_k(t) \}_{k=1}^N \), \( \{ \beta_k(t) \}_{k=1}^N \), \( \{ \eta_k(t) \}_{k=1}^M \), and \( \{ \zeta_k(t) \}_{k=1}^M \) such that
\[
g(t, \tau) = \begin{cases} 
\sum_{k=1}^N \alpha_k(t) \beta_k(\tau), & \text{if } t > \tau \\
\sum_{k=1}^M \eta_k(t) \zeta_k(\tau), & \text{if } t < \tau 
\end{cases}
\]

For integral operators on \( L_2(E) \) for any measurable set \( E \), being finite-rank is equivalent to having a degenerate kernel. We focus on the case where \( E \) as a subset of \( \mathbb{R} \).

**Theorem 5.6.4** Let \( E \in \{ \mathbb{R}, \mathbb{R}_+, \mathbb{R}_- \} \) and let \( K : L_2(E) \to L_2(E) \) be an integral operator with kernel \( g(t, \tau) \). \( K \) is a finite-rank operator on \( L_2(E) \) if and only if \( g(t, \tau) \) is degenerate.

**Proof** See [5] and [78].
This theorem indicates that integral operators with semi-degenerate kernels are infinite-rank operators. Calculating $Ku$ is simplified somewhat if $K$ has a semi-degenerate kernel.

5.6.3 Application to Ordinary Integer-Order Differential Equations

Recall that a system described by an integer-order differential equation can be represented by a convolution operator,

$$x(t) = (Gu)(t) = \int_{-\infty}^{\infty} \tilde{g}(t - \tau) u(\tau) d\tau.$$  

Clearly, this is an integral operator. If $\tilde{g}(t) \in L_1(\mathbb{R})$, then by Theorem 5.6.1, $G$ is a bounded operator on $L_2(\mathbb{R})$. For real-world applications, signals cannot have infinite energy, so it is natural to consider systems as operators from $L_2(\mathbb{R})$ to $L_2(\mathbb{R})$. Thus, we consider systems as integral operators on $L_2(\mathbb{R})$. Note that by Equation 2.12, the kernel of a convolution operator $G$ arising from an integer-order system can be written as

$$\tilde{g}(t) = \sum_{k=1}^{k_n} \sum_{i=1}^{m_k} r_{k_i} \frac{t^{i-1} e^{p_{k_i} t}}{(i-1)!} U_k(t). \quad (5.5)$$

If the system is causal and has only simple poles, Equation 5.5 simplifies to

$$\tilde{g}(t) = \sum_{k=1}^{n} r_{k_i} e^{p_k(t-\tau)} U_s(t - \tau).$$
Let $\alpha_k(t) = r_k e^{p_k t}$ and $\beta_k(\tau) = e^{p_k \tau}$. Then the convolution operator for the system can be written as

$$ (Gf)(t) = \int_{-\infty}^{\infty} \sum_{k=1}^{n} \alpha_k(t) \beta_k(\tau) \mathcal{U}_s(t - \tau) f(\tau) d\tau. $$

Note that the kernel is not degenerate, but only semi-degenerate. Thus, the operator is of infinite-rank. However, for $t > 0$, the integral may be divided into the initial-condition response and the forced response as

$$ (Gf)(t) = \int_{-\infty}^{0} \sum_{k=1}^{n} \alpha_k(t) \beta_k(\tau) \mathcal{U}_s(t - \tau) f(\tau) d\tau $$
$$ + \int_{0}^{\infty} \sum_{k=1}^{n} \alpha_k(t) \beta_k(\tau) \mathcal{U}_s(t - \tau) f(\tau) d\tau $$
$$ = \int_{-\infty}^{0} \sum_{k=1}^{n} \alpha_k(t) \beta_k(\tau) f(\tau) d\tau + \int_{0}^{\infty} \sum_{k=1}^{n} \alpha_k(t) \beta_k(\tau) \mathcal{U}_s(t - \tau) f(\tau) d\tau, $$

since $\mathcal{U}_s(t - \tau) = 1$ for $t > 0$ and $\tau < 0$. The operation associated with the forced response still only has a semi-degenerate kernel and is thus infinite-rank. However, the initial condition response has a degenerate kernel and is thus finite-rank. A similar argument can be made for integer-order systems with repeated poles. It will be shown in Theorem 6.3.1 that for a fractional-order system the initial condition operator is of infinite rank. Because of the presence of $\mathcal{U}_s(t - \tau)$ in the kernel of the forced response, the associated operator is not Hermitian by Theorem 5.6.2. For many systems the initial condition operator turns out to be Hermitian. We will see
the conditions on the impulse response that give Hermitian initial condition operators in Section 6.1.

5.7 Estimation of Eigenvalues for Operators on a Hilbert Space

The following methods may be used for estimating eigenvalues and eigenvectors of compact operators on any Hilbert space.

5.7.1 The Rayleigh-Ritz Method

This method of obtaining eigenvalue estimates was originated by Rayleigh [80] and Ritz [81].

**Definition** Let $\mathcal{H}$ be a Hilbert space, and let $K \in \mathcal{B}(\mathcal{H})$. Define the functionals, $J_K(f)$ and $R_K(f)$ by

$$J_K(f) = \langle Kf, f \rangle,$$

and

$$R_K(f) = \frac{\langle Kf, f \rangle}{\|f\|^2},$$

for all $f \in \mathcal{H}$. $R_K(f)$ is called the Rayleigh quotient.

The heart of the Rayleigh-Ritz method is in the following lemma.

**Lemma 5.7.1** Let $\mathcal{H}$ be a Hilbert space, and let $K \in \mathcal{B}_0(\mathcal{H})$ be a compact Hermitian operator, and let $f \in \mathcal{H}$ such that $\|f\| = 1$. Then $f$ is a stationary point of $\langle Kf, f \rangle$ if
and only if \( f \) is an eigenfunction of \( K \). The stationary values are the corresponding eigenvalues of \( K \).

**Proof** See [78].

The Rayleigh-Ritz method involves selecting a finite basis \( \{ \phi_k \}_{k=1}^N \), the span of which is the subspace \( E_N \subset \mathcal{H} \). Elements of \( \mathcal{H} \) are approximated by elements in \( E_N \). Then the stationary points and values of \( J_K(p) \) for \( p \in E_N \) such that \( \| p \| = 1 \) are found. These approximate the stationary points and values of \( J_K(f) \) for \( f \in \mathcal{H} \), which by Lemma 5.7.1 are the eigenvectors and eigenvalues of the operator \( K \). When the eigenvalue that is being approximated is nonzero, the approximation \( \hat{\lambda}_k \) is no larger in magnitude than the actual eigenvalue \( \lambda_k \); that is, \( |\hat{\lambda}_k| \leq |\lambda_k| \) if \( \lambda_k \neq 0 \) [78]. We call these estimates underestimates.

Computationally, the essence of the Rayleigh-Ritz method is that an eigenvector problem in \( \mathcal{H} \) is replaced by a generalized eigenvector problem in \( E_N \). This is possible because the stationary points of \( J_K(p) \) for \( p \in E_N \) restricted by \( \| p \| = 1 \) for \( 1 \leq m \leq N \) are \( p_m = \sum_{k=1}^N \alpha_{km} \phi_k \), where the \( \alpha_{km} \) are the solutions of the system of equations

\[
\sum_{k=1}^N (J_{\ell k} - \mu_m I_{\ell k}) \alpha_{km} = 0 \tag{5.6}
\]

for \( 1 \leq \ell \leq N \), with \( J_{\ell k} = \langle K \phi_k, \phi_\ell \rangle \) and \( I_{\ell k} = \langle \phi_k, \phi_\ell \rangle \) [78]. The \( \mu_m \) are the stationary values corresponding to the \( p_m \). Computationally, the stationarity of the \( p_m \) and \( \mu_m \) is unimportant. However, this stationarity in instrumental in proving Theorem 5.7.3.
The system of equations in Equation 5.6 can be written as

\[ P \alpha_m = \mu_m Q \alpha_m, \]

where

\[ P = \begin{pmatrix}
\langle K \phi_1, \phi_1 \rangle & \langle K \phi_1, \phi_2 \rangle & \cdots & \langle K \phi_1, \phi_N \rangle \\
\langle K \phi_2, \phi_1 \rangle & \langle K \phi_2, \phi_2 \rangle & \cdots & \langle K \phi_2, \phi_N \rangle \\
\vdots & \vdots & \ddots & \vdots \\
\langle K \phi_N, \phi_1 \rangle & \langle K \phi_N, \phi_2 \rangle & \cdots & \langle K \phi_N, \phi_N \rangle 
\end{pmatrix}, \]

\[ \alpha_m = \begin{pmatrix}
\alpha_{1m} \\
\alpha_{2m} \\
\vdots \\
\alpha_{Nm}
\end{pmatrix}, \]

and

\[ Q = \begin{pmatrix}
\langle \phi_1, \phi_1 \rangle & \langle \phi_1, \phi_2 \rangle & \cdots & \langle \phi_1, \phi_N \rangle \\
\langle \phi_2, \phi_1 \rangle & \langle \phi_2, \phi_2 \rangle & \cdots & \langle \phi_2, \phi_N \rangle \\
\vdots & \vdots & \ddots & \vdots \\
\langle \phi_N, \phi_1 \rangle & \langle \phi_N, \phi_2 \rangle & \cdots & \langle \phi_N, \phi_N \rangle 
\end{pmatrix}. \]

To summarize, the \( \alpha_{km} \) are the entries of the generalized eigenvectors of \( P \) with respect to \( Q \), where the \((\ell, k)\) entry of \( P \) is \( J_{\ell k} \) and the \((\ell, k)\) entry of \( Q \) is \( I_{\ell k} \). The \( \mu_m \) are the corresponding generalized eigenvalues of \( P \) with respect to \( Q \).
5.7.2 The Galerkin Method

The Galerkin method is a slightly different approach to the eigenvalue estimation proposed by Galerkin [26]. As in the Rayleigh-Ritz method, a finite-dimensional subspace \( E_N \subset \mathcal{H} \) is used to determine approximations to the eigenvalues of the Hermitian operator \( K \in \mathcal{B}_0(\mathcal{H}) \). Rather than approximating elements in \( \mathcal{H} \) with elements in \( E_N = \text{span} \{ \phi_k \}_{k=1}^N \), the Galerkin method approximates the operator \( K \) with \( \hat{K} = P_N K P_N \), where \( P_N \) is the orthogonal projection operator from \( \mathcal{H} \) to \( E_N \).

For \( p \in \mathcal{H} \) the eigenvalues and eigenvectors of \( \hat{K} \) satisfy

\[
\mu p = \hat{K} p. \tag{5.7}
\]

Since it is clear that if \( p_m \) is an eigenvector of \( \hat{K} \) then \( p_m \in E_N \), we can make the substitution \( p_m = \sum_{k=1}^N \alpha_{km} \phi_k \), which gives the system of equations

\[
\sum_{k=1}^N (J_{\ell k} - \mu_m I_{\ell k}) \alpha_{km} = 0, \]

for \( 1 \leq \ell \leq N \) as in the Rayleigh-Ritz method. The \( \alpha_{km} \) are the entries of the generalized eigenvectors of \( P \) with respect to \( Q \), where the \((\ell, k)\) entry of \( P \) is \( J_{\ell k} \) and the \((\ell, k)\) entry of \( Q \) is \( I_{\ell k} \). The \( \mu_m \) are the corresponding generalized eigenvalues of \( P \) with respect to \( Q \). The eigenvalues and eigenvectors of \( \hat{K} \), the projected operator, are determined from \( \alpha_{km} \) and \( \mu_m \). The eigenvalues and eigenvectors of \( \hat{K} \) are approximates to those of \( K \). Although the Rayleigh-Ritz method involves approximating
the eigenvectors of $K$ and the Galerkin method involves approximating $K$ itself, the computations involved in both methods are the same.

5.7.3 Overestimates on Eigenvalues

The Rayleigh-Ritz method produces underestimates of positive eigenvalues. We desire to have bounded estimates on the Hankel singular values, that is both an underestimate and an overestimate. Recall that $J_K(p)$ is defined by

$$J_K(p) = \langle Kp, p \rangle.$$ 

The following lemma will be used to facilitate an easier calculation for the overestimates.

**Lemma 5.7.2** Let $K \in \mathcal{B}_0(\mathcal{H})$ be a Hermitian operator. Then

$$J_{K^2}(p) - J_K^2(p) = \|Kp - J_K(p)p\|^2.$$
**Proof** Note that $J_K(p) \in \mathbb{R}$. Then,

\[
J_K^2(p) - J_K^2(p) = \langle K^2 p, p \rangle - J_K(p) \overline{J_K(p)}
\]

\[
= \langle Kp, Kp \rangle - J_K(p) \overline{J_K(p)} - J_K(p) \langle p, Kp \rangle + J_K^2(p)
\]

\[
= \langle Kp, Kp \rangle - \langle Kp, p \rangle \overline{J_K(p)} - J_K(p) \langle p, Kp \rangle + J_K^2(p) \langle p, p \rangle
\]

\[
= \langle Kp - J_K(p)p, Kp - J_K(p)p \rangle.
\]

\[
= \|Kp - J_K(p)p\|^2.
\]

---

**Theorem 5.7.3** Let $K \in \mathcal{B}_0(\mathcal{H})$ be a Hermitian operator. Then for any $p \in \mathcal{H}$ such that $\|p\| = 1$, $K$ has at least one eigenvalue in the interval $I$ given by

\[
I = [J_K(p) - \|Kp - J_K(p)p\|, J_K(p) + \|Kp - J_K(p)p\|].
\]

**Proof** See [78].

The proof of Theorem 5.7.3 makes use of the fact that the eigenvectors of $K$ are the stationary points of $J_K(p)$.

Theorem 5.7.3 along with the Rayleigh-Ritz method allows the calculation of bounded eigenvalue estimates. For a compact Hermitian operator $K$, we apply the Rayleigh-Ritz method to determine an underestimate $\mu_k$ to the eigenvalue $\lambda_k$ of $K$ and an $N$-dimensional approximate $p_k$ to a corresponding eigenvector $\phi_k$ of $K$, noting that $\mu_k = J_K(p_k)$. Then, using $p_k$, we apply Theorem 5.7.3 to obtain an overestimate,
\( \nu_k \) of the eigenvalue \( \lambda_k \) of \( K \), given by
\[
\nu_k = J_K(p_k) + \| Kp_k - J_K(p_k)p_k \|.
\] If the bounds are not sufficiently close, we increase the value of \( N \) and repeat the process.

5.8 Examples

We now look at the second-order system, the resistor-terminated, and inductor-terminated semi-infinite lines as convolution operators on \( L_2(\mathbb{R}) \).

5.8.1 Second-Order System

Recall the second order system introduced in Section 2.4.1, whose transfer function is
\[
G(s) = \frac{-2s}{s^2 + s + \frac{1}{4}},
\]
and whose convolution kernel is
\[
\tilde{g}(t - \tau) = e^{-\frac{t}{2}}(t - \tau - 2)U_s(t - \tau)
= \left( e^{-\frac{t}{2}}(t - 2)e^{\frac{t}{2}} + e^{-\frac{t}{2}}(-\tau e^{\frac{t}{2}}) \right)U_s(t - \tau).
\]

Note that
\[
\int_{-\infty}^{\infty} |g(t - \tau)| \, d\tau = \frac{8}{e} = c_1
\]
and

\[ \int_{-\infty}^{\infty} |g(t - \tau)| \, dt = \frac{8}{e} = c_2. \]

Hence, by Theorem 5.6.1, the convolution operator \( \mathcal{G} \) whose kernel is \( \tilde{g}(t - \tau) \) is a bounded operator with \( \| \mathcal{G} \| \leq \frac{8}{e} \). Note that \( G \in L_\infty(i\mathbb{R}) \) with a maximum value \( \| G \|_\infty = 2 \). Hence, by Theorem 5.5.12, \( \| \mathcal{G} \| = 2 < \frac{8}{e} \).

Because \( \tilde{g}(t - \tau) \notin L_2(\mathbb{R}^2) \), we cannot use Theorem 5.6.3 to determine the compactness of \( \mathcal{G} \). Also note that although \( \tilde{g}(t - \tau) \) is semi-degenerate, it is not degenerate, so \( \mathcal{G} \) is of infinite rank by Theorem 5.6.4. By Theorem 6.5.12, since \( \tilde{g}(t - \tau) \neq \tilde{g}(\tau - t) \), \( \mathcal{G} \) is not Hermitian. Because the convolution operator is an integral operator with an upper limit \( t \), it has no non-zero singular values [82].

Consider the initial-condition response and the forced response given in Equations 2.20 and 2.21,

\[
x_{ic}(t) = \int_{-\infty}^{0} e^{-\frac{t-\tau}{2}} (t - \tau - 2) f(\tau) \, d\tau \\
= \int_{-\infty}^{0} \left( e^{-\frac{1}{2}} (t - 2) e^\frac{\tau}{2} + e^{-\frac{1}{2}} (-\tau e^\frac{\tau}{2}) \right) f(\tau) \, d\tau,
\]

(5.8)
and

\[
x_f(t) = \int_0^t e^{-\frac{t}{2}} (t - \tau - 2) f(\tau) d\tau = \int_0^t \left(e^{-\frac{t}{2}} (t - 2) e^{\frac{\tau}{2}} + e^{-\frac{\tau}{2}} (-\tau e^{\frac{\tau}{2}})\right) f(\tau) d\tau = \int_0^{\infty} \left(e^{-\frac{t}{2}} (t - 2) e^{\frac{\tau}{2}} + e^{-\frac{\tau}{2}} (-\tau e^{\frac{\tau}{2}})\right) U_s(t - \tau) f(\tau) d\tau.
\]

As with \( G \) the operator associated with the forced response has a semi-degenerate, but not degenerate, kernel. Hence, the operator associated with the forced response is an infinite-rank operator. However, in this case, the operator associated with the initial-condition response has a degenerate kernel because the kernel can be written as \( \alpha_1(\tau)\beta_1(\tau) + \alpha_2(\tau)\beta_2(\tau) \), where \( \alpha_1(t) = e^{-\frac{t}{2}}(t - 2) \), \( \beta_1(\tau) = e^{\frac{\tau}{2}} \), \( \alpha_2(t) = e^{-\frac{\tau}{2}} \), and \( \beta_2(\tau) = e^{\frac{\tau}{2}} \). Thus, the associated operator is finite-rank, and is also compact. This is a specific case of the general discussion in Section 5.6.3.

To find the singular values \( \{\sigma_k\} \) and Schmidt pairs \( \{(u_k, w_k)\} \) of the initial condition operator, \( \{w_k(t)\} \) can be selected as the orthonormalization of \( \{\alpha_k(t)\} \), and \( \{u_k(\tau)\} \) can be selected as the orthonormalization of \( \{\beta_k(\tau)\} \). With this in mind, we set \( w_1(t) = e^{-\frac{t}{2}}(t - 1) \) and \( w_2(t) = -e^{-\frac{t}{2}} \) for \( t \geq 0 \), and set \( u_1(\tau) = e^{\frac{\tau}{2}} \) and \( u_2(\tau) = e^{\frac{\tau}{2}}(\tau + 1) \) for \( \tau < 0 \). Note that \( w_1 \) and \( w_2 \) are orthonormal on \( L_2(\mathbb{R}_+) \) and that \( u_1 \) and \( u_2 \) are orthonormal on \( L_2(\mathbb{R}_-) \). We can rewrite Equation 5.8 as

\[
x_{ic}(t) = \int_{-\infty}^0 \left(e^{-\frac{t}{2}}(t - 1)e^{\frac{\tau}{2}} - e^{-\frac{\tau}{2}}e^{\frac{\tau}{2}}(\tau + 1)\right) f(\tau) d\tau = e^{-\frac{t}{2}}(t - 1) \int_{-\infty}^0 e^{\frac{\tau}{2}} f(\tau) d\tau - e^{-\frac{\tau}{2}} \int_{-\infty}^0 e^{\frac{\tau}{2}}(\tau + 1) f(\tau) d\tau. \quad (5.9)
\]
Then for $k \in \{1, 2\}$, $(u_k, w_k)$ are the Schmidt pairs of the initial-condition operator and $\sigma_1 = 1 = \sigma_2$ are the only non-zero singular values of the initial-condition operator. Hence, this operator has a rank of 2. We will see in Chapter 6 that the operator associated with the initial-condition response is a Hermitian operator.

5.8.2 Resistor-Terminated Semi-Infinite Line

Recall that the resistor-terminated semi-infinite line has transfer function

$$G_R(s) = \frac{1}{s^2 + 1}$$

and convolution kernel

$$\tilde{g}_R(t - \tau) = \sum_{k=1}^{2} (-1)^{k-1} E_{t-\tau} \left( \frac{k - 2}{2}, 1 \right) U_s(t - \tau).$$

$G_R \in L_\infty(i\mathbb{R})$ with $\|G\|_\infty = 1$. Hence, $\|G_R\| = 1$ by Theorem 5.5.12. Because $E_{t-\tau} \left( -\frac{1}{2}, 1 \right)$ is neither degenerate nor semi-degenerate, $\tilde{g}_R(t - \tau)$ is neither degenerate nor semi-degenerate. Thus, $G_R$ and the operators associated with the initial-condition and forced responses are of infinite rank. Because $\tilde{g}_R(t - \tau) \neq \tilde{g}_R(\tau - t)$, by Theorem 6.5.12 is not Hermitian. We can do no simple analysis on the convolution operator or the operators associated with the initial-condition and forced responses to determine a Schmidt decomposition.
5.8.3 Inductor-Terminated Semi-Infinite Line

The transfer function of the inductor-terminated semi-infinite line can be written as

\[ G_L(s) = \frac{1}{s^2 + 1} = \frac{\frac{1}{3}}{s^\frac{1}{3} + 1} - \frac{\frac{s^\frac{1}{3} - 2}{3}}{s - s^\frac{2}{3} + 1}. \]  

(5.10)

\( G_L \in L_\infty(i\mathbb{R}) \) with \( \|G\|_\infty = \sqrt{2} \), so by Theorem 5.5.12, \( \|G_L\|_\infty = \sqrt{2} \). Note that in Equation 5.10, \( \frac{1}{s^2 + 1} \) appears. Since this term leads to a non-degenerate convolution kernel, the entire convolution kernel is non-degenerate. Again, the kernel is not even semi-degenerate. Since \( \tilde{g}_L(t - \tau) \neq \tilde{g}(\tau - t) \), by Theorem 6.5.12 \( G_L \) is not Hermitian. Once again, there is very little that can be said about this operator.

5.9 Conclusions

For the second-order system, the forced response was difficult to analyze, and no decomposition for the associated operator was found. However, it was seen that the operator associated with the initial condition response is finite-rank, and a Schmidt decomposition was obtained. For the resistor-terminated and inductor-terminated semi-infinite lines, the convolution operators and operators associated with the forced and initial-condition responses were found to be infinite-rank. It will be seen in Chapter 6 that the operators associated with the initial-condition responses, while of infinite rank, are compact. Because compact operators are more easily analyzed,
we study the operator which takes inputs for $t < 0$ to outputs for $t > 0$, called the Hankel operator.
CHAPTER VI
HANKEL OPERATORS

We have provided a general abstract framework in which convolution operators on $L_2(\mathbb{R})$ can be considered. We now introduce the Hankel operator, which maps inputs for $t < 0$ to outputs for $t > 0$. On $L_2(\mathbb{R}_+)$ the Hankel operator for a system is closely related to the convolution operator on $L_2(\mathbb{R})$ for that system. In this chapter equivalent Hankel operators are defined on $L_2(\mathbb{R}_+)$, $H_2(\mathbb{C}^+)$, $H_2(\mathbb{D})$, and $\ell_2(\mathbb{N})$.

Next, some general results about Hankel operators are presented. We demonstrate the conditions under which the class of fractional-order operators with transfer function $G(s) = \frac{r}{s^{\sigma-a}} + \frac{r}{s^{\sigma-a}}$ have compact Hankel operators. A final result shows that when $q$ is not purely imaginary, the Hankel operator associated with $G(s)$ is either compact or unbounded.

6.1 Representations of Hankel Operators

On each of the Hilbert spaces $L_2(\mathbb{R}_+)$, $H_2(\mathbb{C}^+)$, $H_2(\mathbb{D})$, and $\ell_2(\mathbb{N})$ we define an operator that we call a Hankel operator.
We would like an operator that maps inputs for time $t < 0$ to outputs for time $t > 0$. For a function $f \in L_2(\mathbb{R})$, we define $f_-$ by
\[
f_-(t) = \begin{cases} 
f(t), & t < 0 \\
0, & t > 0
\end{cases}
\]
where $f_-(t)$ represents the input for time $t < 0$. Note that $f_-(t) \in L_2(\mathbb{R}_-) \text{ and } f_-(-t) \in L_2(\mathbb{R}_+)$. Consider $Gf_-$, which is given by
\[
(Gf_-)(t) = \int_{-\infty}^{\infty} \tilde{g}(t - \tau)f_-(\tau)d\tau = \int_{-\infty}^{0} \tilde{g}(t - \tau)f_-(\tau)d\tau
\]
\[
= \int_{0}^{\infty} \tilde{g}(t + \tau)f_-(-\tau)d\tau
\]
(6.1)
under the mapping $\tau \mapsto -\tau$. Comparing Equation 6.1 with Equation 2.15, it is clear that this is a form of the initial-condition response of $G$.

We define the Hankel operator $\Gamma_G : L_2(\mathbb{R}_+) \rightarrow L_2(\mathbb{R}_+)$ associated with $G$ whose convolution kernel is $\tilde{g}(\xi)$ by
\[
(\Gamma_Gu)(t) = \int_{0}^{\infty} \tilde{g}(t + \tau)u(\tau)d\tau.
\]
(6.2)
If $u(t) = f_-(t)$, then the Hankel operator gives the initial-condition response of the system, that is, the output of the system for time $t > 0$ to the input of the system for time $t < 0$. 

146
By Theorem 5.6.2 the adjoint of \( \Gamma \), denoted \( \Gamma^* \), is given by

\[
(\Gamma^* u)(t) = \int_0^\infty \hat{g}(t + \tau) u(\tau) d\tau.
\]

Hence, if \( \hat{g} \) is a real-valued function, \( \Gamma \) is a Hermitian operator. From Theorem 5.6.1 and Theorem 5.6.3, \( \Gamma \) is bounded if \( \hat{g} \in L_1(\mathbb{R}_+) \) and \( \Gamma \) is compact if \( \hat{g} \in L_2(\mathbb{R}_+) \).

The \( s \)-domain representation of \( \Gamma \), denoted \( \Gamma_{s} : H_2(\mathbb{C}^+) \to H_2(\mathbb{C}^+) \), is

\[
(\Gamma_s U)(s) = \Pi_+(G(s)U(-s)),
\]

where \( \Pi_+ \) is the orthogonal projection operator onto \( H_2(\mathbb{C}^+) \), \( G(s) = \mathcal{L}\{\hat{g}(t)\} \), and \( U(-s) = \mathcal{L}\{f_-(t)\} \). \( G(s) \) is called a symbol for \( \Gamma \). For rational polynomials, \( \Pi_+ F(s) \) is calculated by obtaining a partial-fraction expansion for \( F(s) \) and discarding the terms that are not analytic in \( \mathbb{C}^+ \). Other functions, in particular rational polynomials in a non-integer power, do not admit such an expansion. Consequently, there is no known means of calculating the orthogonal projection operator directly in \( H_2(\mathbb{C}^+) \) when fractional-order systems are involved.

The representation of \( \Gamma_{\mathbb{D}} \) on \( H_2(\mathbb{D}) \), denoted \( \Gamma_{\mathbb{D}} : H_2(\mathbb{D}) \to H_2(\mathbb{D}) \) is

\[
(\Gamma_{\mathbb{D}} u)(z) = \Pi_+ (g(z)u(z^{-1})),
\]

where \( \Pi_+ \) is the orthogonal projection operator onto \( H_2(\mathbb{D}) \), \( g(z) = \mathcal{L}\{\hat{g}(t)\} \), and \( U(-s) = \mathcal{L}\{f_-(t)\} \). \( G(s) \) is called a symbol for \( \Gamma_{\mathbb{D}} \). For rational polynomials, \( \Pi_+ F(s) \) is calculated by obtaining a partial-fraction expansion for \( F(s) \) and discarding the terms that are not analytic in \( \mathbb{D} \). Other functions, in particular rational polynomials in a non-integer power, do not admit such an expansion. Consequently, there is no known means of calculating the orthogonal projection operator directly in \( H_2(\mathbb{D}) \) when fractional-order systems are involved.
where $\Pi_+$ is the orthogonal projection operator onto $H_2(\mathbb{D})$, and $g(z)$ is given by

$$g(z) = \frac{G\left(\frac{1-z}{1+z}\right)}{z},$$

$g(z)$ is called a symbol for $\Gamma_g$. Also note that $G(s)$ can be obtained from $g(z)$ using the mapping

$$G(s) = g\left(\frac{1-s}{1+s}\right)\frac{1-s}{1+s}.$$

For rational polynomials in $H_2(\mathbb{D})$, $\Pi_+ f(z)$ is calculated by obtaining a partial-fraction expansion for $f(z)$ and discarding the terms that are not analytic in $\mathbb{D}$. In general the functions $g(z)u(z^{-1})$ do not admit a partial-fraction expansion when $g(z)$ is the symbol for a Hankel operator of a fractional-order system. Thus, there is no known means of calculating the orthogonal projection of such functions directly in $H_2(\mathbb{D})$.

Suppose that $g(z)$ has a Laurent series expansion given by

$$g(z) = \sum_{k=-\infty}^{\infty} g_k z^k.$$
Table 6.1: Hankel Operator Notation.

The representation of $\Gamma_g$ on $\ell_2(\mathbb{N})$, denoted $\Gamma : \ell_2(\mathbb{N}) \rightarrow \ell_2(\mathbb{N})$, is given by

$$
\begin{pmatrix}
  u_0 \\
  u_1 \\
  u_2 \\
  \vdots
\end{pmatrix} =
\begin{pmatrix}
  g_0 & g_1 & g_2 & \cdots \\
  g_1 & g_2 & g_3 & \cdots \\
  g_2 & g_3 & g_4 & \cdots \\
  \vdots & \vdots & \vdots & \ddots
\end{pmatrix}
\begin{pmatrix}
  u_0 \\
  u_1 \\
  u_2 \\
  \vdots
\end{pmatrix},
$$

(6.5)

which can be written as

$$(\Gamma u)_k = \sum_{m=0}^{\infty} g_{m+k}u_m.$$

The matrix in Equation 6.5 is called a Hankel matrix. The entries of a Hankel matrix depend only on the sum of the indices. The sequence $\{g_k\}$ is called a generating sequence for the Hankel operator $\Gamma$. Table 6.1 summarizes the notation we have developed.

Having defined equivalent Hankel operators on $L_2(\mathbb{R}^+)$, $H_2(\mathbb{D})$, $H_2(\mathbb{C}^+)$, and $\ell_2(\mathbb{N})$, we now formally state that these operators are unitarily equivalent.
Theorem 6.1.1

1. Let $\Gamma_G$ be a Hankel operator with symbol $G(s)$. Let

$$g(z) = \frac{G\left(\frac{1}{1+z}\right)}{z}.$$ 

Then $\Gamma_g$ and $\Gamma_G$ are unitarily equivalent operators.

2. Let $\Gamma_g$ be a Hankel operator with symbol $g(z)$. Let

$$G(s) = g\left(\frac{1-s}{1+s}\right)\frac{1-s}{1+s}.$$ 

Then $\Gamma_G$ and $\Gamma_g$ are unitarily equivalent operators.

3. Let $\Gamma_G$ be a Hankel operator with symbol $G(s)$. Let $\tilde{g}(t) = \mathcal{L}^{-1}\{G(s)\}$. Then $\Gamma_G$ and $\Gamma_G$ are unitarily equivalent operators.

4. Let $\Gamma_g$ be a Hankel operator with symbol $g(z)$. $g(z)$ has a Laurent-series expansion

$$g(z) = \sum_{k=-\infty}^{\infty} g_k z^k.$$
Define $\Gamma : \ell_2(\mathbb{N}) \to \ell_2(\mathbb{N})$ by

$$
\begin{pmatrix}
    u_0 \\
    u_1 \\
    u_2 \\
    \vdots
\end{pmatrix}
= \begin{pmatrix}
    g_0 & g_1 & g_2 & \cdots \\
    g_1 & g_2 & g_3 & \cdots \\
    g_2 & g_3 & g_4 & \cdots \\
    \vdots & \vdots & \vdots & \ddots
\end{pmatrix}
\begin{pmatrix}
    u_0 \\
    u_1 \\
    u_2 \\
    \vdots
\end{pmatrix}.
$$

Then $\Gamma$ and $\Gamma_g$ are unitarily equivalent operators.

**Proof** See [73] and [75].

Because the operators $\Gamma_{\tilde{g}}$, $\Gamma_G$, $\Gamma_g$, and $\Gamma$ are unitarily equivalent, henceforth we discuss the Hankel operators in the form that is most convenient for discussion.

### 6.2 Well-Known Results Concerning Hankel Operators

Nehari [60] gives a characterization of the bounded Hankel operators.

**Theorem 6.2.1 (Nehari Theorem)** The Hankel operator $\Gamma$ with generating sequence $\{g_k\}_{k=0}^{\infty}$ is bounded on $\ell_2(\mathbb{N})$ if and only if there exists a function $\phi \in L_\infty(\mathbb{T})$ with $\phi(z) = \sum_{-\infty}^{\infty} \phi_k z^k$ such that

$$
\phi_k = g_k, k \geq 0.
$$
In this case,

\[ \| \Gamma \| = \inf \left\{ \| \phi \|_{\infty} : \phi \in L_{\infty}(\mathbb{T}), \phi = \sum_{k=-\infty}^{\infty} \phi_k z^k, \text{ and } \phi_k = g_k \text{ for all } k \geq 0 \right\}. \]

**Proof** See [60].

Because Hankel operators on \( L_2(\mathbb{R}_+) \) are integral operators whose kernels \( \tilde{g}(t+\tau) \) have a special relationship with the impulse response \( \tilde{g}(\xi) \), there is a condition on \( \tilde{g}(\xi) \) which results in the Hankel operator being compact.

**Theorem 6.2.2** Let \( \tilde{g} \in L_1(\mathbb{R}_+) \). Then \( \Gamma_{\tilde{g}} : L_2(\mathbb{R}_+) \to L_2(\mathbb{R}_+) \) is compact.

**Proof** See [75].

For Hankel operators on \( L_2(\mathbb{T}) \), there is a condition on \( g(z) \) that is equivalent to \( \Gamma_g \in B_0(L_2(\mathbb{T})) \), but first we require two definitions.

**Definition** Define the set \( C(E) = \{ f : f \text{ is continuous on } E \} \). Also, define the set \( C_0(i\mathbb{R}) = \{ F : F(s) \text{ is continuous on } i\mathbb{R} \text{ and } \lim_{|\omega| \to \infty} |F(i\omega)| = 0 \} \). Based on these definitions, \( C_0(i\mathbb{R}) \subset C(i\mathbb{R}) \).

**Theorem 6.2.3** (Hartman’s Theorem) The Hankel operator \( \Gamma_g \) is compact if and only if \( g \in H_\infty(\mathbb{D})^+ + C(\mathbb{T}) \).

**Proof** See [35].

The portion of a symbol \( g(z) \) that is in \( H_\infty(\mathbb{D})^+ \) contributes nothing to the Hankel operator. Hartman’s Theorem states that if the portion of \( g(z) \) that is in \( H_\infty(\mathbb{D}) \) is also in \( C(\mathbb{T}) \), then the associated Hankel operator is compact. This
condition for the compactness of $\Gamma_g$ can easily be converted to a condition for the compactness of $\Gamma_G$.

**Corollary 6.2.4** $\Gamma_G$ is compact if and only if $G \in H_\infty(\mathbb{C}^-) + C_0(i\mathbb{R})$.

**Proof** See [73].

We will refer to both Theorem 6.2.3 and Corollary 6.2.4 as Hartman’s theorem. Theorem 6.2.3 will be used in Section 6.5 to demonstrate the compactness of a class of Hankel operators.

A problem whose solution is relevant to the model-reduction problem and requires the spectral decomposition of the Hankel operator is the Nehari Problem.

**Nehari Problem** Given a Hankel operator $\Gamma$ on $\ell_2(\mathbb{N})$ determine the best $n$-dimensional approximation, $\Gamma_n$ to $\Gamma$.

Recall that by the spectral theorem for compact Hermitian operators, Theorem 5.4.2, if $\Gamma$ is a compact operator, there exist $\{v_n\}$ and $\{w_n\}$ and scalars $\sigma_n$ decreasing to 0 such that

$$\Gamma f = \sum_{k=1}^{\infty} \sigma_k \langle f, v_k \rangle w_k$$

for all $f \in \mathcal{H}$. The singular values and Schmidt pairs prove quite useful in the solution of the Nehari problem. The Adamyan-Arov-Krein theorem [4], or AAK theorem, shows that this problem is well-posed, and gives a limit on how good of an approximation can be found.

**Theorem 6.2.5 (Adamyan-Arov Krein Theorem)** Let $\Gamma$ be a Hankel operator on $\ell_2(\mathbb{N})$ and let $n \geq 0$. Then there exists a Hankel operator $\Gamma_n : \ell_2(\mathbb{N}) \to \ell_2(\mathbb{N})$ of
rank less than or equal to $n$ such that

$$\|\Gamma - \Gamma_n\| = \sigma_{n+1}(\Gamma).$$

**Proof** See [4].

We now specifically consider Hankel operators on $L_2(\mathbb{R})$ for fractional-order systems and demonstrate that Hankel operators of non-integer rational-order systems are of infinite rank.

### 6.3 Integral-Operator Hankel Operators for Fractional-Order Systems

It has already been established in Section 3.4.2 that bounded fractional-order operators can be considered as convolution operators from $L_2(\mathbb{R})$ to $L_2(\mathbb{R})$. Then, let $\mathcal{G} : L_2(\mathbb{R}) \to L_2(\mathbb{R})$ be a fractional-order operator represented as a convolution operator, with impulse response $\hat{g}(t)$ and transfer function $G(s)$. Then $\mathcal{G}$ is given by

$$(\mathcal{G}u)(t) = \int_{-\infty}^{\infty} \hat{g}(t - \tau)u(\tau)d\tau.$$ 

Since $u \in L_2(\mathbb{R}) = L_2(\mathbb{R}_-) \oplus L_2(\mathbb{R}_+)$, $\Pi_-u \in L_2(\mathbb{R}_-)$ and $\Pi_+u \in L_2(\mathbb{R}_+)$. Define $u_+(t) = \Pi_+u(t)$ and $\hat{u}_-(t) = \Pi_+u(-t)$, noting that $\hat{u}_-(t) \in L_2(\mathbb{R}_+)$ and
\[ \hat{u}_-(t) = (\Pi_- u(\tau))|_{\tau=-t}. \] Then \( G \) can be written as

\[
(\mathcal{G}u) (t) = \int_{-\infty}^{\infty} \check{g}(t-\tau)u(\tau)\,d\tau = \int_{-\infty}^{0} \check{g}(t-\tau)u(\tau)\,d\tau + \int_{0}^{\infty} \check{g}(t-\tau)u(\tau)\,d\tau
\]

\[
= -\int_{0}^{\infty} \check{g}(t+\tau)u(-\tau)\,d\tau + \int_{0}^{\infty} \check{g}(t-\tau)u(\tau)\,d\tau
\]

\[
= \int_{0}^{\infty} \check{g}(t+\tau)\hat{u}_-(\tau)\,d\tau + \int_{0}^{\infty} \check{g}(t-\tau)u_+(\tau)\,d\tau
\]

\[
= (\Gamma_g u) (t) + \int_{0}^{\infty} \check{g}(t-\tau)u_+(\tau)\,d\tau,
\]

where \( \Gamma_g : L_2(\mathbb{R}+) \rightarrow L_2(\mathbb{R}+) \) is defined by

\[
(\Gamma_g u) (t) = \int_{0}^{\infty} \check{g}(t+\tau)\hat{u}_-(\tau)\,d\tau,
\]

is a Hankel operator.

Recall Theorem 5.6.4, which says that for any measurable set \( E \), an integral operator from \( L_2(E) \) to \( L_2(E) \) is finite rank if and only if its kernel is degenerate. Applied to integral operator representation of Hankel operators, this means that \( \Gamma_g : L_2(\mathbb{R}+) \rightarrow L_2(\mathbb{R}+) \) is finite rank if and only if \( \check{g}(t + \tau) \) is degenerate; that is, there exist two finite sets of functions, \( \{a_k(t)\}_{k=1}^{N} \) and \( \{b_k(\tau)\}_{k=1}^{N} \) such that

\[
\check{g}(t + \tau) = \sum_{k=1}^{N} a_k(t)\beta_k(\tau).
\]

It has already been shown in Section 5.6.3 that kernels for integer-order Hankel operators with simple poles are degenerate. It is noted that finite sums and finite
products of degenerate kernels yield kernels that are also degenerate. Certain functional forms clearly give degenerate kernels. Kernels that are complex exponentials are degenerate. Kernels of the form \((\alpha t + \beta \tau)^n\) for \(n \in \mathbb{N}\) are degenerate. Other functional forms obviously give non-degenerate kernels. Kernels of the form \((\alpha t + \beta \tau)^{q}\) for \(q \in \mathbb{C}\setminus\mathbb{N}\) are non-degenerate. Kernels containing terms of the form \(\gamma(\nu, a(t + \tau))\) for \(\nu \in \mathbb{C}\setminus\mathbb{N}\) are non-degenerate because there do not exist two finite sets of functions, \(\{a_k(t)\}_{k=1}^N\) and \(\{b_k(\tau)\}_{k=1}^N\) such that

\[
\gamma(\nu, a(t + \tau)) = \int_0^{a(t+\tau)} \xi^{-\nu-1}e^{-\xi}d\xi = \sum_{k=1}^{N} a_k(t)b_k(\tau).
\]

This leads to our next theorem, given in [5].

**Theorem 6.3.1** Let \(n \in \mathbb{N}\) be greater than one, let \(\check{g}(t)\) be given by

\[
\check{g}(t) = \sum_{k=1}^{n} a^{k-1} E_t \left( \frac{k}{n} - 1, a^n \right),
\]

and let \(\Gamma_g : L_2(\mathbb{R}+) \to L_2(\mathbb{R}+)\) be the Hankel operator associated with \(\check{g}(t)\). \(\Gamma_g\) is an infinite-rank operator.

**Proof** Note that since \(n > 1\), \(\check{g}(t)\) will always have the term, \(a E_t \left( -\frac{n-1}{n}, a^n \right)\). Thus, \(\check{g}(t + \tau)\) will have the term given by

\[
a E_{t+\tau} \left( -\frac{n-1}{n}, a^n \right) = a^{n-1} E_{t+\tau} \left( -\frac{n-1}{n}, a(t + \tau) \right).
\]  

(6.7)
\( \gamma(-\frac{n-1}{n}, a(t+\tau)) \) is non-degenerate, so the kernel given by \( \tilde{g}(t+\tau) \) is non-degenerate. Hence, by Theorem 5.6.4, \( \Gamma_y \) is an infinite-rank operator.

Note from Section 3.4.3 that \( \tilde{g}(t) \) is the impulse response for the system with transfer function

\[
G(s) = \frac{1}{s^n - a},
\]

so systems of this type have infinite-rank Hankel operators.

Recall that the Hankel operator maps the prior inputs of a system to its future outputs. The Hankel operator determines the initial condition response of a system. When a Hankel operator has infinite rank, its range is the span of an infinite number of distinct basis functions. An initial-condition response cannot be fully described with a finite number of initial conditions if the Hankel operator has infinite rank. That is, commensurate fractional-order systems are of infinite order, and as such, a finite number of initial conditions is not sufficient to properly account for initialization. Fractional-order systems require an infinite number of initial conditions to properly account for initialization of the system.

6.4 Hankel Operator Equivalences

We will be considering Hankel operators with symbols of the form \( \frac{r}{s^n-a} \). We now show that a Hankel operator whose symbol is of the form \( \frac{r}{s^n-a} \) for \( q \in \mathbb{C}^- \) for \( a \in \mathbb{C} \setminus \{0\} \) also has a symbol \( \frac{\tilde{r}}{s^n-\tilde{a}} \), where \( \tilde{q} \in \mathbb{C}^+ \) and \( \tilde{a} \in \mathbb{C} \setminus \{0\} \).
Theorem 6.4.1 Consider $G_1(s)$ and $G_2(s)$ the symbols for Hankel operators given by

$$G_1(s) = \frac{r}{s^q - a},$$

and

$$G_2(s) = -\frac{r}{s^q - \frac{1}{a}}.$$ 

$G_1(s)$ and $G_2(s)$ give equivalent Hankel operators.

**Proof** Note that a symbol $g_2(z)$ for the operator $\Gamma_{G_2}$, which is unitarily equivalent to $\Gamma_{G_1}$, is given by

$$g_2(z) = -\frac{1}{z} \frac{r}{s^q - \frac{1}{a}}.$$  \hspace{1cm} (6.8)

Note that

$$G_1(s) = \frac{r}{s^q - a} = -\frac{r}{a} \frac{s^q}{s^q - \frac{1}{a}} = -\frac{r}{a} - \frac{r}{s^q - \frac{1}{a}}.$$  \hspace{1cm} (6.9)

Consider the symbol $g_1(z)$ for the operator $\Gamma_{G_1}$, which is unitarily equivalent to $\Gamma_{G_1}$.

$g_1(z)$ is given by

$$g_1(z) = -\frac{r}{a} \frac{1}{z} - \frac{1}{z} \frac{s^q}{s^q - \frac{1}{a}}.$$  \hspace{1cm} (6.10)

Clearly, the first term in Equation 6.10 is not in $H_2(\mathbb{D})$, so an equivalent symbol $g_{1,e}(z)$ for $g_1(z)$ is

$$g_{1,e}(z) = -\frac{1}{z} \frac{s^q}{s^q - \frac{1}{a}} = g_2(z).$$

Hence, $G_1(s)$ and $G_2(s)$ correspond to equivalent Hankel operators.
Corollary 6.4.2 The Hankel operators whose symbols are

\[ G_1(s) = \frac{r}{s^q - a} + \frac{\tau}{s^\eta - \bar{a}} \]

and

\[ G_2(s) = -\frac{r}{s^q - \frac{1}{a}} - \frac{\tau}{s^\eta - \frac{1}{\bar{a}}} \]

are equivalent.

Proof Since

\[ G_1(s) = \frac{r}{s^q - a} + \frac{\tau}{s^\eta - \bar{a}} = \frac{r s^q}{s^q - \frac{1}{a}} + \frac{\tau s^\eta}{s^\eta - \frac{1}{\bar{a}}} = -\frac{r}{a} - \frac{r}{s^q - \frac{1}{a}} - \frac{\tau}{\bar{a}} s^\eta - \frac{1}{\bar{a}} \]

the result follows in the same manner as the result of Theorem 6.4.1.

6.5 Compactness of the Hankel Operator for a Class of Fractional-Order Systems

Before we may apply the algorithm given in Section 7.1 to an operator, we must demonstrate that the operator is compact. We will do so using Hartman’s theorem, Theorem 6.2.3. Before we may apply Hartman’s theorem, we need several well-known results on continuous functions.
Theorem 6.5.1 Let \( f \) and \( g \) be continuous functions from \( X \) to \( \mathbb{C} \) and let \( \alpha, \beta \in \mathbb{C} \). Then \( \alpha f + \beta g \) and \( fg \) are both continuous. Also \( f/g \) is continuous, provided \( g(x) \neq 0 \) for any \( x \in X \).

Proof See [19].

Theorem 6.5.2 Let \( f : X \to Y \) and \( g : Y \to Z \) be continuous functions. Then \( g \circ f \), where \((g \circ f)(x) = g(f(x))\), is a continuous function from \( X \) to \( Z \).

Proof See [19].

Suppose \( G(s) = \frac{1}{s^2 - a} \) with restrictions on \( q \) and \( a \) such that \( G \in L_\infty (i\mathbb{R}) \). Then Theorem 6.5.1 and Theorem 6.5.2 will be used to show \( G(s) \in C (i\mathbb{R}) \).

In order to show that \( G(s) \in C (i\mathbb{R}) \), we will apply Theorem 6.5.1 to \((i\omega)^q - a\). In order to do so, we need that \((i\omega)^q\) is continuous and that \((i\omega)^q \neq a\), which we prove in the next two lemmata.

Lemma 6.5.3 Let \( q \in \mathbb{C}^+ \) and let \( f : \mathbb{R} \to \mathbb{C} \) be given by

\[
f(i\omega) = (i\omega)^q.
\]

Then \( f \) is continuous from \( \mathbb{R} \) to \( \mathbb{C} \).

Proof Let \( u = \text{Re} \,(q) \) and \( v = \text{Im} \,(q) \) and note that \( u > 0 \). Then

\[
f(i\omega) = (i\omega)^q = (e^{i\frac{\pi}{2}} e^{\ln|\omega| + i\text{Arg}(\omega)})^{u + iv}
\]

\[
= \left( e^{\ln|\omega| + i\left(\text{Arg}(\omega) + \frac{\pi}{2}\right)} \right)^{u + iv}
\]

\[
= e^{u \ln|\omega| - v \left(\text{Arg}(\omega) + \frac{\pi}{2}\right)} e^{i\left( v \ln|\omega| + u \left(\text{Arg}(\omega) + \frac{\pi}{2}\right) \right)}.
\]

(6.11)
Since $\omega \in \mathbb{R}$, $\text{Arg}(\omega)$ can be written as

$$\text{Arg}(\omega) = \frac{\pi}{2} (1 - \text{sgn}(\omega)). \quad (6.12)$$

Substituting Equation 6.12 into Equation 6.11 results in

$$f(i\omega) = e^{u \ln |\omega| - v(\pi(1 - \text{sgn}(\omega)))} e^{i(v \ln |\omega| + u(\pi(1 - \text{sgn}(\omega))))}. \quad (6.13)$$

Note that $\ln |\omega|$ and $\text{sgn}(\omega)$ are continuous on $(-\infty, 0)$ and on $(0, \infty)$ and that $e^z$ is continuous for all $z \in \mathbb{C}$. By Theorem 6.5.1 and Theorem 6.5.2, $f$ is continuous on $(-\infty, 0)$ and on $(0, \infty)$.

We now show that $f$ is continuous at $\omega = 0$. Note that

$$|f(i\omega)| = \left| e^{u \ln |\omega| - v(\pi(1 - \text{sgn}(\omega)))} e^{i(v \ln |\omega| + u(\pi(1 - \text{sgn}(\omega))))} \right|$$

$$= \left| e^{u \ln |\omega| - v(\pi(1 - \text{sgn}(\omega)))} \right|$$

$$= e^{u \ln |\omega| - v(\pi(1 - \text{sgn}(\omega)))}$$

$$= |\omega|^u e^{-v(\pi(1 - \text{sgn}(\omega)))} \quad (6.14)$$

Note that $f(i0) = 0$. Let $\epsilon > 0$ be given. Let $\delta > 0$ be given by

$$\delta = \min \left\{ \left( \frac{\epsilon}{2} \right)^{\frac{1}{\pi}} e^{\frac{\pi v}{2}}, \left( \frac{\epsilon}{2} \right)^{\frac{1}{\pi}} e^{\frac{3\pi v}{2}} \right\}.$$
For $\omega > 0$ such that $|\omega| < \delta$, since $u > 0$,

\[
|f(i\omega)| = |\omega|^u e^{-v(\pi(1 - \text{sgn}(\omega)/2))} \\
\leq \left| \left( \frac{\epsilon}{2} \right)^{\frac{1}{u}} e^{\frac{3\pi}{2u}} \right|^u e^{-v\frac{3}{2}\pi} \\
= \frac{\epsilon}{2} e^{\frac{3\pi}{2u}} e^{-v\frac{3}{2}\pi} = \frac{\epsilon}{2} < \epsilon.
\]

Thus, $\lim_{\omega \to 0^+} f(i\omega) = 0$. Similarly, for $\omega < 0$ such that $|\omega| < \delta$,

\[
|f(i\omega)| = |\omega|^u e^{-v(\pi(1 - \text{sgn}(\omega)/2))} \\
\leq \left| \left( \frac{\epsilon}{2} \right)^{\frac{1}{u}} e^{\frac{3\pi}{2u}} \right|^u e^{-v\frac{3}{2}\pi} \\
= \frac{\epsilon}{2} e^{\frac{3\pi}{2u}} e^{-v\frac{3}{2}\pi} = \frac{\epsilon}{2} < \epsilon.
\]

Thus, $\lim_{\omega \to 0^-} f(i\omega) = 0$, and subsequently, $\lim_{\omega \to 0} f(i\omega) = 0 = f(i0)$. Hence, $f$ is continuous at 0.

$f$ is thus continuous on $(-\infty, \infty)$.  

**Lemma 6.5.4** Given $a \in \mathbb{C}$ and $q \in \mathbb{C}^+$ such that $a \neq 0$ and

\[
\arg(a) \neq \frac{\text{Im}(q)}{\text{Re}(q)} \left( \ln |a| \pm \text{Im}(q) \frac{\pi}{2} \right) \pm \text{Re}(q) \frac{\pi}{2}
\]

(6.15)

Then $(i\omega)^q \neq a$ for any $\omega \in \mathbb{R}$. 

162
Proof Let $a \in \mathbb{C}$ and $q \in \mathbb{C}^+$ satisfy Equation 6.15. Suppose that there exists an $\omega_0 \in \mathbb{R}$ such that $(i\omega_0)^q = a$. Let $u = \text{Re}(q)$ and $v = \text{Im}(q)$. Then,

$$|a|e^{i\text{arg}(a)} = \ (i\omega_0)^q = \left(e^{\pm i\frac{\pi}{2}}e^{\ln |\omega_0|}\right)^u + iv = e^{u \ln |\omega_0| + iv} e^{i(u \ln |\omega_0| + uv)}.$$ 

Hence,

$$|a| = e^{u \ln |\omega_0| + uv},$$

(6.16)

and

$$\text{arg} (a) = v \ln |\omega_0| \pm \frac{u \pi}{2}. $$

(6.17)

We solve Equation 6.16 for $\ln |\omega_0|$ to find

$$\ln |\omega_0| = \frac{\ln |a|}{u} \pm \left(\frac{v}{u}\right) \frac{\pi}{2}. $$

(6.18)

Substituting Equation 6.18 into Equation 6.17 results in

$$\text{arg} (a) = \frac{v}{u} \left(\ln |a| \pm \frac{u \pi}{2}\right) \pm \frac{u \pi}{2}. $$

(6.19)

which contradicts Equation 6.15. Hence, $(i\omega)^q \neq a$ for any $\omega \in \mathbb{R}$.

Lemma 6.5.5 will be useful in proving $\Gamma_G$ compact.

163
Lemma 6.5.5 $a \in \mathbb{C} \setminus \{0\}$ and $q \in \mathbb{C}^+$ satisfies

\[
\arg(a) = \frac{\text{Im}(q)}{\text{Re}(q)} \left( \ln |a| \pm \text{Im}(q) \frac{\pi}{2} \right) \pm \text{Re}(q) \frac{\pi}{2},
\]

(6.20)

if and only if $a$ and $q$ satisfy

\[
\arg\left(\frac{1}{a}\right) = \frac{\text{Im}(q)}{\text{Re}(q)} \left( \ln \left|\frac{1}{a}\right| \pm \text{Im}(q) \frac{\pi}{2} \right) \pm \text{Re}(q) \frac{\pi}{2}.
\]

(6.21)

Also, Equation 6.20 is satisfied if and only if

\[
\arg(|a|) = -\text{Im}(q) \left( \ln |a| \pm \text{Im}(q) \frac{\pi}{2} \right) \mp \text{Re}(q) \frac{\pi}{2}. \quad (6.22)
\]

Proof Note that the two values of \(\frac{\text{Im}(q)}{\text{Re}(q)} (\ln |a| \pm \text{Im}(q) \frac{\pi}{2}) \pm \text{Re}(q) \frac{\pi}{2}\) are the same two quantities as \(\frac{\text{Im}(q)}{\text{Re}(q)} (\ln |a| \mp \text{Im}(q) \frac{\pi}{2}) \mp \text{Re}(q) \frac{\pi}{2}\). Equation 6.20 is satisfied if and only if

\[
\arg\left(\frac{1}{a}\right) = -\arg(a) = -\frac{\text{Im}(q)}{\text{Re}(q)} \left( \ln |a| \pm \text{Im}(q) \frac{\pi}{2} \right) \mp \text{Re}(q) \frac{\pi}{2}
\]

\[
= \frac{\text{Im}(q)}{\text{Re}(q)} \left( -\ln |a| \mp \text{Im}(q) \frac{\pi}{2} \right) \mp \text{Re}(q) \frac{\pi}{2}
\]

\[
= \frac{\text{Im}(q)}{\text{Re}(q)} \left( \ln \left|\frac{1}{a}\right| \mp \text{Im}(q) \frac{\pi}{2} \right) \mp \text{Re}(q) \frac{\pi}{2}.
\]
which proves the first part of the lemma. Equation 6.20 is satisfied if and only if

\[
\arg (\pi) = -\arg (a) = -\frac{\text{Im} (q)}{\text{Re} (q)} \left( \ln |a| \pm \text{Im} (q) \frac{\pi}{2} \right) \mp \text{Re} (q) \frac{\pi}{2}
\]

which proves the second part of the lemma.

We now show that \( \Gamma \) is a compact operator.

\textbf{Theorem 6.5.6} Suppose that \( G(s) = \frac{1}{s-a} \) with \( q \in \mathbb{C} \setminus i \mathbb{R} \) and \( a \in \mathbb{C} \) such that \( a \neq 0 \) and

\[
\arg (a) \neq \frac{\text{Im} (q)}{\text{Re} (q)} \left( \ln |a| \pm \text{Im} (q) \frac{\pi}{2} \right) \pm \text{Re} (q) \frac{\pi}{2}.
\] (6.23)

Then \( \Gamma \) is compact.

\textbf{Proof} We will prove that \( G(s) \in C_0 (i \mathbb{R}) \) so we may apply Hartman’s theorem.

Suppose that \( q \in \mathbb{C}^- \). Then by Theorem 6.4.1, \( \Gamma \) also has symbol \( \hat{G}(s) = \frac{1}{s-q-a}\hat{a} \), and by Lemma 6.5.5 this symbol satisfies the condition in Equation 6.23 for \( \hat{q} = -q \) and \( \hat{a} = \frac{1}{\hat{a}} \). Thus, without loss of generality, we may assume that \( q \in \mathbb{C}^+ \).

By Lemma 6.5.3, \( (i \omega)^q \) is continuous from \( \mathbb{R} \) to \( \mathbb{C} \). By Theorem 6.5.1, \( (i \omega)^q-a \) is continuous for \( a \in \mathbb{C} \) since \( a \) is continuous. By Lemma 6.5.4, \( (i \omega)^q-a \neq 0 \) for any \( \omega \in \mathbb{R} \), so \( (i \omega)^q-a \neq 0 \) for any \( \omega \in \mathbb{R} \). Thus, by Theorem 6.5.1, \( G(s) = \frac{1}{(i \omega)^q-a} \) is continuous because 1 and \( (i \omega)^q-a \) are continuous with \( (i \omega)^q-a \neq 0 \) for all \( \omega \in \mathbb{R} \).

Note that \( \lim_{|\omega| \to \infty} |G(i \omega)| = 0 \) Hence, \( G(s) \in C_0 (i \mathbb{R}) \subset C(i \mathbb{R}) \), and subsequently, by Hartman’s theorem, \( \Gamma \) is compact. 

\[165\]
**Corollary 6.5.7** Suppose that $G(s) = \frac{r}{s^2 - a} + \frac{r}{s^2 - \pi}$ with $q \in \mathbb{C} \setminus i\mathbb{R}$ and $a, r \in \mathbb{C}$ such that $a \neq 0$ and

$$\arg(a) \neq \frac{\text{Im}(q)}{\text{Re}(q)} \left( \ln |a| \pm \frac{\pi}{2} \right) \pm \frac{\pi}{2}.$$  \hspace{1cm} (6.24)

Then $\Gamma_G$ is compact.

**Proof** Note that $G_1(s) = \frac{r}{s^2 - a}$ and $G_2(s) = \frac{r}{s^2 - \pi}$ satisfy the conditions of Theorem 6.5.6, using Lemma 6.5.5 for $G_2(s)$. Thus, as shown in the proof of Theorem 6.5.6, $G_1(s), G_2(s) \in C(i\mathbb{R})$. By Theorem 6.5.1, $(G_1(s) + G_2(s)) \in C(i\mathbb{R})$. Further, $\lim_{|\omega| \to \infty} |G(i\omega)| = 0$. Subsequently, by Hartman’s theorem, $\Gamma_G$ is compact. \hfill \Box

If $q$ is real then the condition as in Equation 6.23 is simpler. We state this formally.

**Corollary 6.5.8** Suppose that $G(s) = \frac{1}{s^2 - a}$ with $q \in (0, \infty)$ and $a \in \mathbb{C}$ such that $a \neq 0$ and

$$\arg(a) \neq \pm q \frac{\pi}{2}.$$  \hspace{1cm} (6.25)

Then $\Gamma_G$ is compact.

**Proof** If $q \in (0, \infty)$, then $\text{Re}(q) = q > 0$ and $\text{Im}(q) = 0$. $a$ satisfies the condition of Equation 6.23, and Theorem 6.5.6 is applied to give the result. \hfill \Box

As a final corollary to Theorem 6.5.6, we demonstrate the compactness of a class of operators, whose Hankel singular values we will estimate in Section 7.2.3.
Corollary 6.5.9 Let \( G(s) = \frac{1}{s^2+1} \) where \( q \in (0, \infty) \) such that \( q \neq 4k + 2 \) for any \( k \in \mathbb{N} \). Then \( \Gamma_G \) is a compact operator.

Proof Let \( q \in (0, \infty) \) such that \( q \neq 2(2k+1) \) for any \( k \in \mathbb{N} \). Suppose that \( \arg (-1) = \frac{\pi}{2} \) or \( \arg (-1) = -\frac{\pi}{2} \). Note that \( \arg (-1) = (2k+1)\pi \) for some \( k \in \mathbb{Z} \).

Hence, either

\[
q = \frac{2}{\pi} \arg (-1) = \frac{2}{\pi} (2k+1)\pi = 2(2k+1)
\]

for some \( k \in \mathbb{Z} \), which contradicts either \( q \in (0, \infty) \) or \( q \neq 2(2k+1) \), or

\[
q = -\frac{2}{\pi} \arg (-1) = -\frac{2}{\pi} (2k+1)\pi = -2(2k+1)
\]

for some \( k \in \mathbb{Z} \), which contradicts either \( q \in (0, \infty) \) or \( q \neq 2(2k+1) \). Thus, Equation 6.25 is satisfied. By Corollary 6.5.8, \( \Gamma_G \) is compact.

We next demonstrate the conditions under which the Hankel operator for the fundamental, linear conjugate-order system is unbounded.

Theorem 6.5.10 Suppose that \( G(s) = \frac{r}{s-a} + \frac{r}{s-a} \) with \( q \in \mathbb{C} \setminus i\mathbb{R} \) and \( a, r \in \mathbb{C} \) such that \( a \neq 0 \) and

\[
\arg (a) = \frac{\text{Im} (q)}{\text{Re} (q)} \left( \ln |a| \pm \text{Im} (q) \frac{\pi}{2} \right) \pm \text{Re} (q) \frac{\pi}{2}.
\]  \( (6.26) \)

Then \( \Gamma_G \) is unbounded.
**Proof** Note that by Nehari’s theorem, $\Gamma_g$ is bounded if and only if there exists a symbol $g(z)$ of $\Gamma_g$ such that $g \in H_\infty(\mathbb{D})$. An equivalent statement is that $\Gamma_G$ is bounded if and only if there exists a symbol $G(s)$ of $\Gamma_G$ such that $G \in H_\infty(\mathbb{C}^+)$. 

Define $u = \text{Re}(q)$ and $v = \text{Im}(q)$. Suppose $G \in H_\infty(\mathbb{C}^+)$, then $G \in L_\infty(i\mathbb{R})$, so there exists an $M \in (0, \infty)$ such that $G(i\omega) \leq M$ for all $\omega \in \mathbb{R}$. This can be rewritten as

$$\frac{1}{G(i\omega)} = \frac{((i\omega)^q - a)((i\omega)^\overline{q} - \overline{a})}{r((i\omega)^q - \overline{a}) + \tau((i\omega)^q - a)} \geq \frac{1}{M} > 0 \quad (6.27)$$

for all $\omega \in \mathbb{R}$.

Then, by Equation 6.26,

$$\text{arg} \left( a^{\overline{q}} \right) = \text{arg} \left( e^{\frac{\ln |a| + \text{arg}(a)}{u + iv}} \right)$$

$$= \text{arg} \left( e^{\frac{\ln |a| + \text{arg}(a)(u - iv)}{u^2 + v^2}} \right)$$

$$= \text{arg} \left( e^{\frac{u \ln |a| + \text{arg}(a) + (\text{arg}(a) - v \ln |a|)}{u^2 + v^2}} \right)$$

$$= \text{arg} \left( e^{\frac{u \ln |a| + \text{arg}(a) + (\text{arg}(a) - v \ln |a|)}{u^2 + v^2}} \right)$$

$$= \frac{u \ln |a| + \text{arg}(a) + (\text{arg}(a) - v \ln |a|)}{u^2 + v^2}$$

$$= \frac{u \ln |a| + \text{arg}(a) + (\text{arg}(a) - v \ln |a|)}{u^2 + v^2}$$

$$= \frac{v \ln |a| + \text{arg}(a) + (\text{arg}(a) - v \ln |a|)}{u^2 + v^2}$$

$$= \frac{v \ln |a| + \text{arg}(a) + (\text{arg}(a) - v \ln |a|)}{u^2 + v^2}$$

$$= \frac{\pi}{2}.$$
Hence, \(-i(a)^{\frac{1}{q}} \in \mathbb{R}\). Choose \(\omega_0 = -i(a)^{\frac{1}{q}}\). Then

\[
(i\omega_0)^q - a = \left(i(-i(a)^{\frac{1}{q}})^q\right) - a = a^q - a = a - a = 0 < \frac{1}{M}.
\]

Therefore \(G \notin L_\infty (i\mathbb{R})\), so \(G \notin H_\infty (\mathbb{C}^+)\), and \(\Gamma_G\) is unbounded.

**Corollary 6.5.11** Suppose that \(G(s) = \frac{r}{s^n - a} + \frac{r}{s^n - \bar{a}}\) with \(q \in \mathbb{C}\setminus i\mathbb{R}\) and \(a, r \in \mathbb{C}\) such that \(a \neq 0\). If \(\Gamma_G\) is not compact, then \(\Gamma_G\) is unbounded.

**Proof** \(a\) and \(q\) satisfy either Equation 6.24 or Equation 6.26. If \(a\) and \(q\) satisfy the former, then, by Corollary 6.5.7, \(\Gamma_G\) is compact. Otherwise, by Theorem 6.5.10, \(\Gamma_G\) is unbounded.

Recall the regions in the \((u, v)\) plane for a fixed \(a\) in Section 4.4.1 and the regions in the \((\ln |a|, \arg (a))\) plane for fixed \(q\) in Section 4.4.3 such that \(G(s) = \frac{r}{s^n - a} + \frac{r}{s^n - \bar{a}}\) corresponds to a stable, causal system. The borders of these regions correspond to the \(q\) or \(a\) for which \(\Gamma_G\) is an unbounded operator. The regions correspond to he \(q\) or \(a\) for which \(\Gamma_G\) is a nonzero, compact operator. Finally, the exterior of the regions and the borders correspond to the \(q\) or \(a\) for which \(\Gamma_G\) is zero.

We also show that Hankel operators with symbol \(G_1(s) = \frac{r}{s^n - a} + \frac{r}{s^n - \bar{a}}\) are Hermitian.

**Theorem 6.5.12** The Hankel operator with symbol

\[
G(s) = \frac{r}{s^n - a} + \frac{r}{s^n - \bar{a}}
\]

169
is Hermitian.

**Proof** Let $\tilde{g}(t)$ be the impulse response of $G(s)$. Note that by Theorem 6.1.1 $\Gamma_G$ and $\Gamma_g$ are unitarily equivalent. Thus, $\Gamma_G$ is Hermitian if and only if $\Gamma_g$ is Hermitian. Since $\tilde{g}(t)$ is a real-valued function by Theorem 4.3.1, by Theorem 5.6.2, $\Gamma_g$ is Hermitian. 

6.6 Examples

We now consider the Hankel operators for the second-order system, as well as the resistor-terminated and inductor-terminated semi-infinite lines.

6.6.1 Second-Order Example

Recall the second order system introduced in Section 2.4.1, whose transfer function is

$$G(s) = \frac{-2s}{s^2 + s + \frac{1}{4}},$$

and whose impulse response is

$$\tilde{g}(t) = e^{-t/4}(t - 2)U_s(t).$$

Note that $G(s)$ is a symbol for $\Gamma_G : L_2(i\mathbb{R}) \to L_2(i\mathbb{R})$. We showed that $G(s) \in L_\infty(i\mathbb{R})$ in Section 5.8.1, and it is easily shown that $G(s) \in C(i\mathbb{R})$. Hence, by Hartman’s theorem, $\Gamma_G$ is compact. A symbol for the unitarily equivalent Hankel
operator $\Gamma_g : H_2 (\mathbb{D}) \to H_2 (\mathbb{D})$ is

$$
g(z) = \Pi_+ \frac{1}{z} G \left( \frac{1 + z}{1 - z} \right) = \Pi_+ \left( \frac{8(z^2 - 1)}{z(z - 3)^2} \right) = \frac{16(5z - 3)}{9(z - 3)^2}.
$$

Since $g(z) \in C(\mathbb{T})$, by Hartman’s theorem, $\Gamma_g$ is compact. In fact, since $\Gamma_g$ is unitarily equivalent to $\Gamma_G$ and $\Gamma_G$ is compact, the compactness of $\Gamma_g$ follows. Note that $g(z) \in L_\infty(\mathbb{T})$ and that

$$
g(z) = -\frac{16}{27} + \frac{16}{27} z + \frac{112}{243} z^2 + \frac{176}{729} z^3 + \frac{80}{729} z^4 + \frac{304}{6561} z^5 + \frac{368}{19683} z^6 + \cdots.
$$

The generating sequence for the unitarily equivalent operator $\Gamma : \ell_2 (\mathbb{N}) \to \ell_2 (\mathbb{N})$ is

$$\{g_k\} = \left\{ -\frac{16}{27}, \frac{16}{27}, \frac{112}{243}, \frac{176}{729}, \frac{80}{729}, \frac{304}{6561}, \frac{368}{19683}, \cdots \right\}.
$$

Because $g(z) \in L_\infty(\mathbb{T})$, by Nehari’s theorem, $\Gamma_g$ is bounded. $\Gamma_g$ is compact because it is unitarily equivalent to $\Gamma_G$ and $\Gamma_g$, compact operators. The representation for the Hankel operator $\Gamma_G$ on $L_2 (\mathbb{R}_+)$ is

$$
(\Gamma_G f)(t) = \int_0^\infty e^{-\frac{|t+\tau|}{2}} (t + \tau - 2)f_-(\tau) d\tau
$$

for $t > 0$. $\tilde{g}(t) \in L_1(\mathbb{R}_+)$, so by Theorem 6.2.2, $\Gamma_G$ is compact. It was demonstrated in Section 5.8.1 that this is a rank-two operator with two singular values of unity.
6.6.2 Resistor-Terminated Semi-Infinite Line

Recall that the resistor-terminated semi-infinite line has transfer function

\[ G_R(s) = \frac{1}{s^2 + 1} \]

and impulse response

\[ \tilde{g}_R(t) = \sum_{k=1}^{2} (-1)^{k-1} E_t \left( \frac{k-2}{2}, 1 \right). \]

A symbol for \( \Gamma \) is \( G_R(s) \). Since \( G_R(s) \in C(i\mathbb{R}) \), by Hartman’s theorem \( \Gamma_G \) is compact. A symbol for the unitarily equivalent Hankel operator \( \Gamma_g : H_2(\mathbb{D}) \to H_2(\mathbb{D}) \) is

\[ g_R(z) = \Pi_+ \left( \frac{G_R \left( \frac{1+z}{1-z} \right)}{z} \right) = \frac{1}{z \left( \sqrt{\frac{1+z}{1-z}} + 1 \right)} - \frac{1}{2z}, \]

which is in \( C(\mathbb{T}) \). Again, by Hartman’s theorem, \( \Gamma_g \) is compact. Using the Laurent series expansion for \( g_R(z) \), we obtain a generating sequence for the unitarily equivalent Hankel operator \( \Gamma : \ell_2(\mathbb{N}) \to \ell_2(\mathbb{N}) \) as

\[ \{ g_{R,k} \} = \left\{ \frac{1}{4}, 0, \frac{1}{16}, 0, \frac{1}{32}, 0, \frac{5}{256}, 0, \frac{7}{512}, \cdots \right\}. \quad (6.29) \]
Because $g_R(z) \in L_\infty(i\mathbb{R})$, by Nehari’s theorem $\Gamma$ is bounded. The representation of $\Gamma_g : L_2(\mathbb{R}_+) \to L_2(\mathbb{R}_+)$ is

$$(\Gamma_g f)(t) = \int_0^{\infty} \sum_{k=1}^{2} (-1)^{k-1} E_{t+\tau} \left( \frac{k-2}{2}, 1 \right) f(\tau) d\tau.$$ 

It was shown in [8] that $\tilde{g}_R(t) \in L_1(\mathbb{R}_+)$ using the representation of Miller and Ross for $\tilde{g}_R(t)$. It follows that $\Gamma_g$ is compact.

The discussion in Section 6.3 applies to this Hankel operator, and $\Gamma_g$ is an infinite-rank operator. Note that $\frac{1}{2} \neq 4k + 2$ for any $k \in \mathbb{Z}$. Application of Corollary 6.5.9 and Theorem 6.5.12 give that $\Gamma_g$ is a compact, Hermitian operator. Recall that $G_R$ is not Hermitian. The results for this Hankel operator are with one exception the same as those obtained for the second-order system. Both Hankel operators are bounded, compact, and Hermitian. The difference is that the Hankel operator for the second-order system is finite-rank while the Hankel operator for the resistor-terminated semi-infinite line is infinite-rank.

### 6.6.3 Inductor-Terminated Semi-Infinite Line

Recall that the inductor-terminated semi-infinite line has transfer function

$$G_L(s) = \frac{1}{s^{\frac{3}{2}} + 1}$$

and impulse response

$$\tilde{g}_L(t) = F_{\frac{3}{2}}(1, t).$$
A symbol for $\Gamma$ is $G_L(s)$. By Hartman’s theorem, since $G_L(s) \in C(iR)$, $\Gamma_G$ is compact. A symbol for the unitarily equivalent Hankel operator $\Gamma_g : H_2(D) \to H_2(D)$ is

$$g_L(z) = \Pi_+ \left( \frac{G_L \left( \frac{1+z}{1-z} \right)}{z} \right) = \frac{1}{z \left( \left( \frac{1+z}{1-z} \right)^{\frac{3}{2}} + 1 \right)} - \frac{1}{2z}.$$

Because $g_L(z) \in C(T)$, $\Gamma_g$ is compact. Using the Laurent series expansion for $g_L(z)$, we obtain a generating sequence for $\Gamma : \ell_2(N) \to L_2(R_+)$ as

$$\{g_{L,k} \} = \left\{ \frac{3}{4}, 0, -\frac{5}{16}, 0, \frac{3}{32}, 0, -\frac{9}{256}, 0, \frac{5}{512}, \cdots \right\}. \quad (6.30)$$

Because $g_L(z) \in L_\infty(T)$, by Nehari’s theorem $\Gamma$ is bounded. The representation of $\Gamma_G$ is

$$(\Gamma_G f)(t) = \int_0^\infty F_\frac{3}{2} \left( 1, t + \tau \right) f(\tau) d\tau.$$

Because the sum in the definition of the $F$-function is infinite, it is more difficult to determine whether $\tilde{g}_L(t)$ is integrable or not. However, because $\Gamma$ is unitarily equivalent to a compact Hankel operator $\Gamma_g$, $\Gamma$ is itself compact.

This Hankel operator is an infinite-rank operator as per the discussion in Section 6.3. Note that $\frac{3}{2} \neq 4k + 2$ for any $k \in Z$. Application of Corollary 6.5.9 and Theorem 6.5.12 give that $\Gamma_G$ is a compact, Hermitian operator. Like the resistor-terminated semi-finite line, the inductor-terminated line has a Hankel operator that is bounded, compact, Hermitian, and infinite-rank.
We have discussed four representations of Hankel operators on four isomorphic Hilbert spaces. Conditions under which a Hankel operator is bounded or compact are discussed. We have related the Hankel operator of a fundamental, linear conjugate-order system of order $q$ with the Hankel operator of another fundamental, linear complex order system with order $-q$. Sufficient conditions under which the fundamental, linear conjugate-order system has a compact Hankel operator were established. We now present an algorithm by which the Hankel singular values of a fractional-order system may be approximated.
CHAPTER VII

ESTIMATING THE HANKEL SINGULAR VALUES OF FRACTIONAL-ORDER SYSTEMS

A method to approximate the Hankel singular values of a fractional-order system is given. This algorithm improves on the method given in [8] by also providing upper bounds on the Hankel singular values. The algorithm is demonstrated on a second-order system as an example. The algorithm is then applied to a class of fractional-order operators of the form $G(s) = \frac{a}{s^{2} + a}$. Finally, the algorithm is applied to a class of fractional-order operators of the form $G(s) = \frac{1}{s^{4} + 1}$.

7.1 Methodology

The method we use to determine bounded estimates of the Hankel singular values for fractional-order systems is an application of the Rayleigh-Ritz method for eigenvalue approximation given in Section 5.7. This method is only applicable for compact, Hermitian operators and utilizes the equivalence of Hankel operators in different Hilbert spaces. Recall that $H_{2}(\mathbb{C}^+) \cong L_{2}(\mathbb{R}^+) \cong H_{2}(\mathbb{D}) \cong \ell_{2}(\mathbb{N})$ and that there are unitarily equivalent representations for the Hankel operator on each of the isomorphic Hilbert spaces, given in Theorem 6.1.1. Because it is convenient to describe a system
by its transfer function, we assume that the fractional-order system whose Hankel singular values we wish to determine is given as a transfer function $G(s) \in L_\infty(i\mathbb{R})$.

The following terminology is used throughout the description of the algorithm. $G(s)$ is the transfer function for the system. $G(s)$ is also a symbol for the Hankel operator, $\Gamma_G : \mathcal{H}_2(\mathbb{C}^+) \to \mathcal{H}_2(\mathbb{C}^+)$.

$g(z)$ is a symbol for the Hankel operator $\Gamma_g : \mathcal{H}_2(\mathbb{D}) \to \mathcal{H}_2(\mathbb{D})$. $\Gamma$ is the Hankel operator from $\ell_2(\mathbb{N})$ to $\ell_2(\mathbb{N})$.

1. Choose the dimension $N$ of the subspace to be used for the Rayleigh-Ritz method.

2. Determine the symbol $g(z)$ of the Hankel operator $\Gamma_g$ on $\mathcal{H}_2(\mathbb{D})$ that is unitarily equivalent to $\Gamma_G$ using

$$g(z) = \Pi_+ \left( \frac{G\left(\frac{1-z}{1+z}\right)}{z} \right).$$

3. Determine the first $(2N-2)$ coefficients of the Laurent series $g(z) = \sum_{k=0}^{\infty} g_k z^k$. Note that $\Gamma : \ell_2(\mathbb{N}) \to \ell_2(\mathbb{N})$ is the infinite Hankel matrix of all the coefficients with positive index of the Laurent series for $g(z)$. $\Gamma$ is unitarily equivalent to $\Gamma_g$ and to $\Gamma_G$.

4. Construct the truncated Hankel matrix $\hat{\Gamma}$ as

$$\hat{\Gamma} = \begin{pmatrix} g_0 & g_1 & \cdots & g_{N-1} \\ g_1 & g_2 & \cdots & g_N \\ \vdots & \vdots & \ddots & \vdots \\ g_{N-1} & g_N & \cdots & g_{2N-2} \end{pmatrix}.$$  

(7.1)
5. Determine the eigenvalues $\{\mu_k\}$ of $\hat{\Gamma}$. These are approximations to the eigenvalues of $\Gamma$.

6. Determine the normalized eigenvectors $\{\rho_k\}$ of $\hat{\Gamma}$. These are approximations to the eigenvectors of $\Gamma$.

7. Choose an integer $k$ with $1 \leq k \leq N$. Determine $p_k(z)$ given by

$$p_k(z) = \left(1, z, z^2, z^3, \ldots, z^{N-1}\right) \rho_k.$$ 

$p_k(z)$ is an approximation to the eigenvector of $\Gamma_g$, and $\|p_k(z)\| = 1$ since $\rho_k$ is normalized. Also note that $\mu_k = J_{\Gamma_g}(p_k) = \langle (\Gamma_g p_k)(z), p_k(z) \rangle$ is an approximation to the corresponding eigenvalue of $\Gamma_g$.

8. Calculate $\Gamma_g p_k(z)$.

9. Calculate $e_{\Gamma_g}(p_k) = \|\Gamma_g p_k(z) - \mu_k p_k(z)\|$.

10. The $k^{th}$ non-zero eigenvalue of $\Gamma_G$ is in the interval $[\mu_k, \mu_k + e_{\Gamma_g}(p_k)]$ for $\mu_k > 0$ or the interval $[\mu_k - e_{\Gamma_g}(p_k), \mu_k]$ for $\mu_k < 0$.

11. The $k^{th}$ non-zero singular value of $\Gamma_G$ is in the interval $[|\mu_k|, |\mu_k| + e_{\Gamma_g}(p_k)]$.

This algorithm is an application of the Rayleigh-Ritz method discussed in Section 5.7. The estimation for the Hankel singular values is done in $\ell_2(\mathbb{N})$ using
\( E_N = \mathbb{R}^N \), where \( \mathbb{R}^N \) is the set of \( N \)-tuples with real entries, with the standard basis

\[
\{ \phi_k \} = \left\{ \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \\ \vdots \\ 0 \end{pmatrix}, \ldots, \begin{pmatrix} 0 \\ 0 \\ \vdots \\ 1 \end{pmatrix} \right\}.
\]

Using this basis it is clear that

\[
\langle \hat{\Gamma} \phi_k, \phi_\ell \rangle = \hat{\Gamma}_{\ell k}
\]

and

\[
\langle \phi_k, \phi_\ell \rangle = \begin{cases} 1, & k = \ell \\ 0, & k \neq \ell \end{cases}
\]

Hence, the estimates of the Hankel singular values of \( \Gamma_g \) are the eigenvalues of \( \hat{\Gamma} \).

The calculation of the overestimates is done in \( H_2(\mathbb{D}) \), using the subspace \( E_N = \text{span} \left( \{ z^k \}_{k=0}^{N-1} \right) \), which is isomorphic to \( \mathbb{R}^N \).

### 7.2 Hankel Singular Values for Some Real-Order Systems

We first demonstrate this method with the second-order system presented throughout this text. We then apply the algorithm to two classes of fractional-order systems.
7.2.1 Second-Order Example

Recall the second-order system introduced in Section 2.4.1, whose transfer function is

\[ G(s) = \frac{-2s}{s^2 + s + \frac{1}{4}}, \]

has two non-zero Hankel singular values that are both unity. We choose \( N = 2 \) as the dimension of the subspace to be used in the Rayleigh-Ritz method. Recall from Section 6.6.1 that a symbol \( g(z) \) for \( \Gamma_g \) is

\[ g(z) = \frac{16(5z - 3)}{9(z - 3)^2}, \]

\[ = -\frac{16}{27} + \frac{16}{27}z + \frac{112}{243}z^2 + \frac{176}{729}z^3 + \frac{80}{6561}z^4 + \frac{304}{19683}z^5 + \frac{368}{6561}z^6 + \cdots. \]

Hence, \( \hat{\Gamma} \) is given by

\[ \hat{\Gamma} = \begin{pmatrix} -\frac{16}{27} & \frac{16}{27} \\ \frac{16}{27} & \frac{112}{243} \end{pmatrix}, \quad (7.2) \]

which has eigenvalues

\[ \{\mu_k\} = \{-0.8587, 0.7270\} \quad (7.3) \]

and eigenvectors

\[ \{\rho_k\} = \begin{Bmatrix} \begin{pmatrix} 0.9122 \\ -0.4097 \end{pmatrix}, \begin{pmatrix} 0.4097 \\ 0.9122 \end{pmatrix} \end{Bmatrix}. \quad (7.4) \]
Subsequently, $p_1(z)$ and $p_2(z)$ are

$$p_1(z) = -0.4097z + 0.9122$$

and

$$p_2(z) = 0.9122z + 0.4097.$$  

Note that $p_1(z)$ and $p_2(z)$ are the eigenvectors of the Hankel operator whose symbol is $-\frac{16}{27} + \frac{16}{27}z$, not those of the Hankel operator whose symbol is $g(z)$. Then $(\Gamma gp_1)(z)$ and $(\Gamma gp_2)(z)$ are

$$(\Gamma gp_1)(z) = \frac{7.866z - 7.050}{(z - 3)^2}$$  \hspace{1cm} (7.5)$$

and

$$(\Gamma gp_2)(z) = \frac{4.182z + 2.6800}{(z - 3)^2}.$$  \hspace{1cm} (7.6)$$

$e_{\Gamma g}(p_1) = 0.3770$ and $e_{\Gamma g}(p_2) = 0.4648$. Thus, the Hankel singular values can be approximated by $\sigma_1 \in [0.8587, 1.236]$ and $\sigma_2 \in [0.7270, 1.192]$. This method was repeated for increasing values of $N$. Figure 7.1 shows the results.

Both the estimates and the upper bounds converge quickly to $\sigma_1$ and $\sigma_2$. In this example a sixth-order subspace yields less than 5% error in the estimate. The estimates converge more quickly than the upper bounds.

For $N > 3$ the singular values $\sigma_k$ for $k > 2$ are on the order of $10^{-16}$. Because the difference in orders of magnitude between $\sigma_2$ and $\sigma_3$ is so great, the $\sigma_k$ for $k \geq 3$ are considered zero.
Figure 7.1: Estimates (-) and Error Bounds (- -) of $\sigma_1$ and $\sigma_2$ for $G(s) = \frac{-2s}{s^2 + s + \frac{1}{4}}$.

7.2.2 Hankel Singular Values for $\frac{a}{s^2 + a}$

Let $G(s)$ be the system whose transfer function is

$$G(s) = \frac{a}{s^2 + a}.$$ 

By Theorem 6.5.6 and Theorem 6.5.12, $\Gamma_G$ is compact and Hermitian. Using the method presented in Section 7.1, estimates for the first ten Hankel singular values for the $G(s)$ were calculated for various $a \in (0, 10]$. The specific values of $a$ that were
Table 7.1: Hankel Singular Value Bounds for $\frac{a}{s^2 + a}$.

The singular value estimates were equal to each other to six decimal places as $a$ varied. Similarly, the upper bounds on the singular values were equal to each other to six decimal places as $a$ varied. Table 7.1 shows these results. This leads to the following conjecture.

**Conjecture 7.2.1** Fix $q \in \mathbb{R}\setminus\{0\}$. If $a \in \mathbb{R}\setminus\{0\}$, the Hankel singular values of $G(s) = \frac{a}{s^2 + a}$ do not depend on the value of $a$. 

\[
\left\{ \frac{1}{10}, \frac{1}{9}, \frac{1}{8}, \frac{1}{7}, \frac{1}{6}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{1}{2}, \frac{1}{3}, \frac{1}{2}, \frac{1}{5}, \frac{1}{10}, \frac{1}{5}, \frac{1}{10}, \frac{1}{10}, \frac{1}{3}, \frac{4}{5}, \frac{9}{10}, \frac{1}{10}, \frac{1}{5}, \frac{9}{10}, \frac{1}{3}, \frac{4}{5}, \frac{9}{10}, \frac{1}{10}, \frac{1}{5}, \frac{9}{10}, \frac{1}{3}, \frac{4}{5}, \frac{9}{10}, \frac{1}{10}, \frac{1}{5}, \frac{9}{10}, \frac{1}{3}, \frac{4}{5}, \frac{9}{10}, \frac{1}{10}, \frac{1}{5}, \frac{9}{10}, \frac{1}{3}, \frac{4}{5}, \frac{9}{10} \right\}. \quad (7.7)
\]
7.2.3 Hankel Singular Values for $\frac{1}{s^q+1}$ with $q \in (0, 1]$

Let $G(s)$ be the system whose transfer function is given by

$$G(s) = \frac{1}{s^q + 1},$$

for $q \in (0, 1)$. For all such $q$, Corollary 6.5.9 gives that $\Gamma_G$ is a compact operator, and Theorem 6.5.12 gives that $\Gamma_G$ is a Hermitian operator.

Using the method presented in Section 7.1, estimates for the first ten Hankel singular values of $G(s)$ were calculated. Figure 7.2 shows the estimates of the first Hankel singular value, also called the Hankel norm, for $G(s)$ with $q \in (0, 2)$, as well as an upper bound on the Hankel norm. The curves for the estimate and the upper bound can hardly be distinguished. For a closer view of the results, Figure 7.3 shows the Hankel norm of $G(s)$ for $q \in (0, 1]$. Figure 7.4 through Figure 7.12 show the estimates of the second through tenth Hankel singular values of $G(s)$ with $q \in (0, 1)$, as well as an upper bound on the Hankel singular value. The estimates are more easily obtained for $q \in (1, 2)$ than for $q \in (0, 1)$. In particular, the estimates for the third through tenth Hankel singular values are most difficult to obtain for $q$ in the neighborhood of $\frac{1}{3}$.

Recall that the system $G_1(s) = \frac{1}{s+1}$ is a rank 1 system whose only Hankel singular value is $\sigma_1 = \frac{1}{2}$. Figure 7.2 demonstrates that $\lim_{q \to 1} \sigma_1 \left( \frac{1}{s^q+1} \right) = \frac{1}{2}$. Figure 7.4 through Figure 7.12 demonstrate that for $2 \leq k \leq 10$, $\lim_{q \to 1} \sigma_k \left( \frac{1}{s^q+1} \right) = 0$. These observations reinforce the results obtained.

\]
7.2.4 An Interpretation of the Hankel Singular Values for \( \frac{1}{\sigma_{n+1}} \) with \( q \in (0, 1] \)

\( \sigma_{n+1} \) provides a lower bound on the error in Hankel norm between \( \mathcal{G} \) and an \( n \)-dimensional approximation to \( \mathcal{G} \) [75]. Because this error is absolute, we may obtain lower bound on the percent error in Hankel norm between \( \mathcal{G} \) and an \( n \)-dimensional approximation by the relation

\[
e_n(G(s)) = \frac{\sigma_{n+1}(G(s))}{\sigma_1(G(s))}.
\]

The estimates of \( e_n(G(s)) \), the percent errors in Hankel norm between \( \mathcal{G} \) and an \( n \)-dimensional approximation, are given by

\[
\hat{e}_n(G(s)) = \frac{\hat{\sigma}_{n+1}(G(s))}{\hat{\sigma}_1(G(s))},
\]

where \( \hat{\sigma}_k(G(s)) \) is the estimate of the \( k \)th Hankel singular value of \( G(s) \). Upper and lower bounds on the percent error are given by

\[
\hat{e}_{u,n}(G(s)) = \frac{\hat{\sigma}_{n+1}(G(s))}{\hat{\sigma}_{u,1}(G(s))}
\]

and

\[
\hat{e}_{l,n}(G(s)) = \frac{\hat{\sigma}_{u,n+1}(G(s))}{\hat{\sigma}_1(G(s))},
\]

respectively, where \( \hat{\sigma}_{u,k}(G(s)) \) is the upper bound on the estimate of the \( k \)th Hankel singular value of \( G(s) \). Figures 7.13 through 7.21 show the estimates of the percent

7.3 Examples

We now apply the algorithm presented in Section 7.1 to the resistor-terminated and inductor-terminated semi-infinite lines.

7.3.1 Resistor-Terminated Semi-Infinite Line

The Hankel-singular-value approximation technique presented in Section 7.1 was applied to the resistor-terminated semi-infinite line whose transfer function is

\[ G_R(s) = \frac{1}{s^{1/2} + 1}. \]

This is a particular case of the system that was considered in Section 7.2.2, where the first ten Hankel singular values of \( G_R(s) \) were estimated using \( E_{400} \), a 400-dimensional subspace of \( L_2(\mathbb{T}) \). Because we desire to find the Hankel singular values of this system, we will use \( E_{800} \), an 800-dimensional subspace, which is an extension of \( E_{400} \), in our approximation. Table 7.2 shows the Hankel-singular-value estimates using \( E_{800} \), the upper bound using \( E_{400} \), and the upper bound using \( E_{800} \). The better of the upper bounds is given in bold type.

For \( M > N \) and \( E_N \subset E_M \), \( E_M \) can provide no worse an estimate on the Hankel singular values of a system. However, the upper bounds provided using \( E_M \) are not necessarily better. In fact, for \( 6 \leq k \leq 10 \), the upper bound provided by \( E_{400} \) proved to be a better bound. \( E_{800} \) did provide a better upper bound for \( 1 \leq k \leq 5 \).

We now consider the return on the computation investment on using an 800-dimensional subspace instead of a 400-dimensional subspace. The increase in $\hat{\sigma}_1$ is a mere $9.99 \times 10^{-4}\%$. For calculating the Hankel norm, very little is gained by increasing the dimension of the subspace. The increase in $\hat{\sigma}_5$ is 3.49\%, which is a modest gain, but probably not worth the effort. The most gain is in $\hat{\sigma}_{10}$, which is increased by 31.53\%. The decrease in upper bound ranges from 0.0176\% for $\hat{\sigma}_1$ to 24.97\% for $\hat{\sigma}_5$. The upper bound is actually worse for $\hat{\sigma}_k$ when $6 \leq k \leq 10$.

Roughly 90\% of the computation time is taken with the calculation of the upper bounds. Increasing the dimension of the subspace from 400 to 800 tripled the time that it took to calculate the upper bound. Thus, the benefits in accuracy of an

upper bound gained by increasing the dimension of the subspace are outweighed by the computation time.

Next, a 1,200-dimensional subspace $E_{1,200}$ is used in the approximation of the Hankel singular values for $G_R(s)$. The upper bounds determined by using $E_{400}$ and $E_{800}$ are kept. Table 7.3 shows these results, as well as the maximum possible error of the estimates. At worst, there is 17% error, with the most possible error in $\hat{\sigma}_7$. Table 7.4 shows the minimum possible percent error between the resistor-terminated semi-infinite line and a $k^{th}$-order approximation, calculated with the Hankel singular value estimates.

</table>

Recall that $\hat{G}_R(s)$, a fifth-order approximation to $G_R(s)$, is given by

$$\hat{G}_R(s) = \frac{13.39s^4 + 470.4s^3 + 1501s^2 + 470.4s + 13.39}{s^5 + 124.49s^4 + 1592.4s^3 + 2623s^2 + 481.5s + 14.39}$$

We can use the algorithm of Section 7.1 to determine the norm of $\Gamma_G - \hat{\Gamma}_G$, which is the Hankel norm of $G_R(s) - \hat{G}_R(s)$. Performing the approximation in a 400-dimensional subspace gives that $\|\Gamma_G - \hat{\Gamma}_G\|$ is between 0.0238471 and 0.0282865. The percent error between $\Gamma_G$ and $\hat{\Gamma}_G$ is between 8.60% and 10.20%. The best fifth-order approximation has 3.366% error. The error for $\hat{\Gamma}_G$ is comparable to the 9.526%-error achievable by the optimal third-order approximation. Because the reduction in complexity from a fifth-order system to a third-order system is small, if 10.20%
error is acceptable, then it is better to use $\hat{G}_R(s)$ than to calculate the optimal third-order approximation.

7.3.2 Inductor-Terminated Semi-Infinite Line

The Hankel-singular-value approximation technique presented in Section 7.1 was applied to the inductor-terminated semi-infinite line whose transfer function is

$$G_L(s) = \frac{1}{s^2 + 1}.$$  

This is a particular case of the system that was considered in Section 7.2.3, where the first ten Hankel singular values of $G_L(s)$ were estimated using $E_{400}$ a 400-dimensional subspace of $L_2(\mathbb{T})$. Table 7.5 shows the Hankel singular value estimates, an upper bound on the estimates, and a maximum possible error for each estimate. The maximum possible error in the Hankel singular value estimates is less than 7.5%. Because this error is so low, no larger subspaces will be used to approximate the Hankel singular values. Table 7.4 shows the minimum possible percent error between the inductor-terminated semi-infinite line and $k^{th}$-order approximation, calculated with the Hankel singular value estimates. Comparing the minimum possible errors for the inductor-terminated semi-infinite line with those of the resistor-terminated semi-infinite line, it is possible to achieve lower error with a $k^{th}$-order approximation to the inductor-terminated semi-infinite line than with a $k_0^{th}$-order approximation to the resistor-terminated semi-infinite line.

</tbody>
</table>

Recall that $\hat{G}_L(s)$, a sixth-order approximation to $G_L(s)$, is given by

$$\hat{G}_L(s) = \frac{13.39s^4 + 470.4s^3 + 1501s^2 + 470.4s + 13.39}{s^5 + 111.1s^4 + 1135.39s^4 + 1592.4s^3 + 1612.1s^2 + 471.4s + 13.39}.$$ 

Once again we use the algorithm of Section 7.1 to determine the norm of $\Gamma_G - \hat{\Gamma}_G$, which is the Hankel norm of $G_L(s) - \hat{G}_L(s)$. Performing the approximation in a 60-dimensional subspace gives that $\|\Gamma_G - \hat{\Gamma}_G\|$ is between 0.0400563 and 0.0400598. This degree of accuracy is sufficient, so we will not use a larger subspace. The percent error between $\Gamma_G$ and $\hat{\Gamma}_G$ is approximately 4.51%. The best sixth-order approximation has 0.0363% error. The percent error for $\hat{\Gamma}_G$ is comparable to the optimal second-order approximation, which may have a minimum of 3.599% error. If 4.51% error is acceptable, a second-order approximation can achieve that error while admitting a
less complicated approximation. In this case it may be worthwhile to determine a
second-order approximation that gives about 4.5% error.

7.4 Conclusions

In this chapter the details of the application of the Rayleigh-Ritz method to the
estimation of the Hankel singular values of fractional-order systems were presented.
The algorithm was validated with the second-order example and applied to simple
fractional-order systems of the form $G(s) = \frac{1}{s^q - a}$ for various $q \in (0, 2)$. The first
ten Hankel singular values were calculated. From the results, the Hankel singular
values estimates are more accurate for $q \in (1, 2)$ than they are for $q \in (0, 1)$, using
the same dimensional subspace. These Hankel singular values have been used to
give approximations to the minimal percent errors achievable in approximating the
fractional-order system with a system whose order is an integer between zero and
ten. The Hankel singular values of the resistor-terminated semi-infinite line have
been given to at most 17% error and the Hankel singular values of the inductor-
terminated semi-infinite line have been given to at most 8% error. We now apply this
algorithm to approximate the Hankel norms of a class of conjugate-order systems.
CHAPTER VIII

ESTIMATION OF THE HANKEL NORM FOR A CLASS OF
CONJUGATE-ORDER SYSTEMS

We now consider a class of conjugate-order systems with transfer functions of the form
\[ G(s) = \frac{\frac{1}{s^q+1}}{s^q+1} + \frac{\frac{1}{s^q+1}}{s^q+1}. \]
We demonstrate that \( G(s) \) corresponds to a compact Hermitian operator. Values of \( q \) are selected for which the Hankel-norm approximation is done. These values are selected to utilize the equivalent symbols of \( G(s) \).

8.1 Preliminary Considerations

We will be using the method developed in Section 7.1 to estimate the Hankel norm of the conjugate-order system

\[ G(s) = \frac{\frac{1}{s^{q}+1}}{s^{q}+1} + \frac{\frac{1}{s^{q}+1}}{s^{q}+1}. \]  \hspace{1cm} (8.1)

For \( q \in \mathbb{C}^+ \) such that \((\text{Re } (q) - 1)^2 + (\text{Im } (q))^2 \neq 1\), \( G(s) \) satisfies the conditions of Corollary 6.5.7, and hence, \( \Gamma_G \) is compact. Note that if \( G(s) \) corresponds to a stable, anticausal system, \( \Gamma_G = 0 \). By Theorem 6.5.12, \( \Gamma_G \) is Hermitian.

We apply Theorem 4.4.3 to \( G(s) \) to determine the set of \( q \) for which \( G(s) \) corresponds to a stable, causal system. The set of \( q \) is shown in Figure 8.1. This set
Figure 8.1: Set of \( q = u + iv \) for which \( G(s) = \frac{r}{s^q - (\tau - v)} + \frac{\tau}{s^q - (c - iv)} \) corresponds to a stable, causal system.

consists of two disjoint regions in the \((u, v)\)-plane. The first region is the open disk of unity radius centered at \((1, 0)\), and the second region is the open disk of unity radius centered at \((-1, 0)\). Notice that for no \( q \in i \mathbb{R} \setminus \{0\} \) does \( G(s) \) correspond to a stable, causal system.

Note that

\[
G(s) = \frac{r}{s^q - a} + \frac{\tau}{s^q - \bar{a}},
\]

where \( r = \tau = \frac{1}{2} \) and \( a = \bar{a} = -1 \). Then, by Corollary 6.4.2, the Hankel operator with symbol \( -\frac{\frac{1}{2}}{s^q + 1} - \frac{\frac{1}{2}}{s^{-\frac{1}{2}} + 1} \) is the same as the Hankel operator with symbol \( \frac{\frac{1}{2}}{s^q + 1} + \frac{\frac{1}{2}}{s^{-\frac{1}{2}} + 1} \).
because $\frac{r}{r} = \frac{r}{r} = \frac{1}{2}$ and $\frac{1}{a} = \frac{1}{a} = 1$. Also note that, for this system, the Hankel operator is the same for a given $q \in \mathbb{C}$ and its complex conjugate.

Because the Hankel singular values for $G(s)$ and $-G(s)$ are the same, the Hankel singular values of $G(s) = \frac{\frac{1}{s} + \frac{1}{s}}{s+1}$ are equal for $q = u + iv$, $q = u - iv$, $q = -u + iv$ and $q = -u - iv$. Thus, we will calculate Hankel norms for systems where $q$ has positive real part and positive imaginary parts.

8.2 Estimation

The points shown in Figure 8.2 are the values of $q$ that will be considered. The circle $D_0^+(-1)$ centered at $q = 1$ with unit radius indicates the set of $q$ for which $\Gamma_G$ is an unbounded operator. Thus, the points on this circle are marked with squares and are ignored. The points outside of the circle are marked with circles and are the $q$ for which $G(s)$ corresponds to a stable, anticausal system, so $\Gamma_G = 0$. The points marked with stars are the $q$ to which the Hankel-norm approximation algorithm of Section 7.1 will be applied. We will call this set $\mathcal{P}$.

We use the method presented in Section 7.1 with an eight-hundred dimensional subspace to obtain bounded estimates of the Hankel norm of $G(s)$ for each $q \in \mathcal{P}$. Figure 8.3 and Figure 8.4 show the results of these estimations. Using symmetry, these results are extended to $q$ with negative imaginary or negative real parts. As $q$ gets closer to $D_0^+(-1)$, $\|\Gamma_G\|$ increases without bound. Thus, to prevent a few values from dominating the graph and obscuring the general trend, the maximum
Figure 8.2: Set of $q = u + iv$ for which the Hankel norm $G(s) = \frac{r}{s\sqrt{(e^{i\sigma})}} + \frac{r}{s\sqrt{(e^{-i\sigma})}}$ is calculated.

The equivalence of the Hankel operator for $G(s)$ with $q$ and $\overline{q}$ is used to obtain the Hankel-norm approximations for $\text{Im}(q) < 0$. Figure 8.5 shows these values, and Figure 8.6 shows a contour plot of these values. Figure 8.7 shows a contour plot of the Hankel norms estimated for $q \in \mathbb{C}$.

value shown in Figure 8.3 is 2. Figure 8.4 shows a contour plot of this data. Note that the curve on the Re $(q)$ axis is the curve shown in Figure 7.2, which is to be expected.
Figure 8.3: Estimates of the Hankel norm of $G(s)$ with $q \in \mathbb{C}$ such that $0 \leq \Re(q) \leq 2$ and $0 \leq \Im(q) \leq 1$.

Figure 8.6: Contour Plot of the Estimates of the Hankel norm of $G(s)$ with $q \in \mathbb{C}$ such that $0 \leq \text{Re} (q) \leq 2$ and $-1 \leq \text{Im} (q) \leq 1$. 
Figure 8.7: Contour Plot of the Estimates of the Hankel norm of $G(s)$ with $q \in \mathbb{C}$ such that $-2 \leq \text{Re} (q) \leq 2$ and $-1 \leq \text{Im} (q) \leq 1$. 
8.3 Conclusions

In this chapter the Hankel norm of the conjugate-order system $G(s) = \frac{\frac{1}{s^4} + \frac{1}{s^4}}{s^4 + 1}$ has been estimated. The function that maps $q \in \mathbb{C}$ to the Hankel norm of $G(s)$ is symmetric about the Re ($q$) and Im ($q$) axes. The Hankel norms for $q \in (0, 2)$ match the Hankel norms obtained in the previous chapter. The results given in this chapter are consistent with the analysis of conjugate-order systems given in Chapter 4. This chapter demonstrates the the Hankel singular value estimation algorithm given in Section 7.1 can be applied to systems of conjugate order as well as to systems of real order.
CHAPTER IX

CONCLUSIONS AND FUTURE WORK

The material presented in this work represents the first steps in the determination of a spectral decomposition of the Hankel operator for fractional-order systems. An algorithm for computing the Hankel singular values of a fractional-order system has been presented. This algorithm has been applied to a class of fractional-order systems and a class of conjugate-order systems. The algorithm has also been applied to two specific fractional-order systems, the resistor-terminated and inductor-terminated semi-infinite lines.

The Hankel norm of a fractional-order system can be calculated using the method provided in Section 7.1. This calculation provides the maximum ratio of energy retrievable from the system in the future to the amount of energy delivered to the system in the past. This is an important consideration for fractional-order systems that are used as energy-storage devices. An application of this work determining the efficiency of energy storage of an ultracapacitor bank taking into account both charging and discharging losses.

The algorithm in Section 7.1 can be used to obtain information about finite-rank approximations for fractional-order systems. This method can be applied to calculate the Hankel norm of the error between a fractional-order system and a finite-
rank approximation, which provides a measure of the accuracy of the approximation. The \((k + 1)\)th Hankel singular value of a fractional-order operator obtained using this method offers the smallest achievable error between the system and a \(k\)th-order approximation. For example, a fifth-order approximation for the resistor-terminated semi-infinite line was found using a standard approximation technique. The algorithm of Section 7.1 was applied to determine the Hankel norm of the error between the resistor-terminated semi-infinite line and the fifth-order approximation. The error was determined to be 8.6%. Applying the algorithm to determine the Hankel singular values of the resistor-terminated semi-infinite line gave only 5.42% error for the best possible fifth-order approximation.

Although we have a method by which the singular values of the Hankel operator for a fractional-order system may be estimated, the solution of the Nehari problem requires the Schmidt pairs of the Hankel operator. The algorithm in Section 7.1 does provide approximations to the Schmidt pairs of the Hankel operator for a fractional-order system. However, no bound on the accuracy of those Schmidt-pair estimates is inherently obtained in the process.

A rank-\(k\) approximation to the Hankel operator can be obtained, but because there is error between the actual Schmidt pairs and those obtained by the algorithm of Section 7.1, there is no guarantee on the accuracy of the rank-\(k\) approximation. Further study is necessary to determine a bound on the accuracy of the Schmidt-pair estimates, and subsequently a bound on the degree by which a rank-\(k\) approxima-
ation to the Hankel operator using these estimates differs from the optimal rank- \( k \) approximation.

A problem that is left for future work which builds on this dissertation is the solution of the \( H_\infty \)-control problem. The problem itself must be formulated in such a manner as to allow fractional-order systems as a plant, controller, or both plant and controller. Two possibilities immediately present themselves for systems of real and commensurate order. The first is using coprime factorizations over \( \mathbb{C}^q \cap H_\infty (\mathbb{C}^+) \), and the second using the mapping \( s \mapsto w^{\frac{1}{q}} \) and coprime factorizations over \( \mathbb{C}^r \cap H_\infty (\mathcal{W}) \) where \( \mathcal{W} = \{ w \in \mathbb{C} : |\arg (w)| < \frac{\pi}{q} \} \). Possible formulations are even more difficult for conjugate-order systems.

An approach analogous to the state-space approach for integer-order systems should also be considered. That approach will require the formulation of the fractional-order system as an abstract Cauchy problem of the form \( \dot{x}(t) = Ax(t) + Bu(t) \), where \( A \) and \( B \) are operators on an infinite-dimensional space, and \( A \) probably has infinite rank. Also required is acquiring the strongly continuous semigroup generated by \( A \). This approach is a standard one in the study of many infinite-dimensional systems [29, 21]. The difficulty in this approach lies in formulating the fractional-order system as an abstract Cauchy problem.

</table>
\( E_t(q) \) The function of Miller and Ross

\( \mathbb{F} \) A field, typically either \( \mathbb{C} \) or \( \mathbb{R} \)

\( F_q(a,t) \) The \( F \)-Function, the Green’s function for \( \int_0^t x(t) - ax(t) = u(t) \)

\( \Gamma \) A Hankel operator on \( \ell_2(\mathbb{N}) \)

\( \Gamma_G \) A Hankel operator on \( H_2(\mathbb{C}^+) \)

\( \Gamma_g \) A Hankel operator on \( H_2(\mathbb{D}) \)

\( \Gamma\gamma \) A Hankel operator on \( L_2(\mathbb{R}_+) \)

\( \Gamma(z) \) The (complete) gamma function

\( \Gamma(a,z) \) The upper incomplete gamma function

\( \gamma(a,z) \) The lower incomplete gamma function

\( \gamma^*(a,z) \) The entire lower incomplete gamma function

\( H_2(\mathbb{D}) \) The set \( \{ g \in L_2(\mathbb{T}) : g(z) \text{ is analytic in } \mathbb{D} \} \)

\( H_2(\mathbb{C}^+) \) The set \( \{ F \in L_2(i\mathbb{R}) : F(s) \text{ is analytic in } \text{Re}(s) > 0 \} \)

\( H_2(\mathbb{C}^-) \) The set \( \{ F \in L_2(i\mathbb{R}) : F(s) \text{ is analytic in } \text{Re}(s) < 0 \} \)

\( H_\infty(\mathbb{C}^+) \) The set \( \{ G \in L_\infty(i\mathbb{R}) : G(s) \text{ is analytic in } \text{Re}(s) > 0 \} \)

\( \text{Im}(z) \) The imaginary part of \( z \)

\( \mathcal{L}\{x(t)\} \) The bilateral Laplace transform of \( x(t) \)

\( L_2(\mathbb{R}) \) The set \( \{ f : \int_{-\infty}^{\infty} |f(t)|^2 \, dt < \infty \} \)
$L_2(\mathbb{R}_+)$ The set \( \{ f \in L_2(\mathbb{R}) : f(t) = 0 \text{ for } t < 0 \} \)

$L_2(\mathbb{R}_-)$ The set \( \{ f \in L_2(\mathbb{R}) : f(t) = 0 \text{ for } t \geq 0 \} \)

$L_2(i\mathbb{R})$ The set \( \left\{ \hat{f} : \int_{-\infty}^{\infty} \left| \hat{f}(j\omega) \right|^2 \, d\omega < \infty \right\} \)

$L_2(\mathbb{T})$ The set \( \left\{ g : \int_{-\infty}^{\infty} \left| g\left( e^{j\theta} \right) \right|^2 \, d\theta < \infty \right\} \)

$L_\infty(i\mathbb{R})$ The set \( \{ G : |G(j\omega)| \text{ has a uniform bound on } j\mathbb{R} \} \)

$\lambda_n(K)$ For $K \in \mathcal{B}(\mathcal{H})$, the $n^{th}$ eigenvalue of $K$

$\mathbb{N}$ The natural numbers; the set \( \{0, 1, 2, 3, \ldots \} \)

$\Pi_+$ The orthogonal projection operator from $L_2(i\mathbb{R})$ onto $H_2(\mathbb{C}^+)$ or from $L_2(\mathbb{T})$ onto $H_2(\mathbb{D})$

$\Pi_-$ The orthogonal projection operator from $L_2(i\mathbb{R})$ onto $H_2(\mathbb{C}^-)$ or from $L_2(\mathbb{T})$ onto $H_2(\mathbb{D})^\perp$

$\Pi_E$ The projection operator from $\mathcal{H}$ onto $E \subset \mathcal{H}$

$\mathbb{R}$ The real numbers

$\mathbb{R}^N$ The set of all $N$-tuples with real entries

$\mathbb{R}_+$ The positive real numbers, the set \( \{ x \in \mathbb{R} : x > 0 \} \)

$\mathbb{R}_-$ The negative real numbers, the set \( \{ x \in \mathbb{R} : x < 0 \} \)

$\mathbb{R}[s]$ The ring of polynomials in $s$ with coefficients in $\mathbb{R}$

$\mathbb{R}(s)$ The field of ratios of $\mathbb{R}[s]$; the set \( \left\{ \frac{R(s)}{A(s)} : A(s), B(s) \in \mathbb{R}[s] \right\} \)

$R_{q,u}(a,t)$ The $R$-Function, the Green’s function for \( \frac{d^q}{dt^q} x(t) - ax(t) = \frac{d^p}{dt^p} u(t) \)
range \((K)\) \: For \(K : A \rightarrow B\), the range of \(K\), the set 
\[ \{ b \in B : b = Ka \text{ for some } a \in A \} \]

rank \((K)\) \: For an operator \(K\), the dimension of range\((K)\)

\(\text{Re} (z)\) \: The real part of \(z\)

\(RH_\infty (\mathbb{C}^+)\) \: The set \(H_\infty (\mathbb{C}^+) \cap \mathbb{R}(s)\)

\(S\) \: The Schwartz space of rapidly decreasing functions on \(\mathbb{R}\)

\(\text{sgn} (r)\) \: The signum of \(r\), for \(r \in \mathbb{R}\), \(\text{sgn} (r) = \frac{r}{|r|}\)

\(\sigma_n (K)\) \: For \(K \in \mathcal{B} (\mathcal{H})\), the \(n^{th}\) singular value of \(K\)

\(T\) \: The unit circle; the set \(\{z \in \mathbb{C} : |z| = 1\}\)

\(\mathcal{U}_s (t)\) \: The unit step function, \(\mathcal{U}_s (t) = \begin{cases} 1, & t \in [0, \infty) \\ 0, & t \in (-\infty, 0) \end{cases}\)

\(\mathbb{Z}\) \: The integers; the set \(\{\cdots -2, -1, 0, 1, 2, \cdots \}\)
